CHAPTER 1  
Introduction

This reference provides conceptual and how-to information about scripting in Macromedia Director MX 2004, and also provides reference descriptions and examples for the scripting application programming interfaces (APIs) that you use to write scripts.

The scripting APIs are the means by which you access the functionality of Director through script to add interactivity to a movie. By using these APIs, you can create interactive functionality that is identical to that provided by the prewritten behaviors that are shipped with Director, in addition to functionality that is more powerful and more varied than that provided by the prewritten behaviors.

The prewritten behaviors enable you to add basic interactive functionality to a movie, such as moving the playhead to a frame number or marker, or zooming in when a user clicks a sprite. They also enable non-interactive functionality such as sprite animation, media loading, and frame navigation. The scripting APIs enable you to extend and customize these types of functionality.

Intended audience

This reference is intended for you if you want to do any of the following:

• Extend the existing functionality of prewritten behaviors by using script.
• Add functionality to a movie by using script instead of prewritten behaviors.
• Add more powerful, varied, and custom functionality to a movie than that provided by prewritten behaviors.

This reference is intended to provide all the information, from basic to advanced, you need to add interactivity to your movies by using script. Therefore, you do not need to have any prior scripting experience to write effective scripts in Director.

Regardless of your experience level with Director, Lingo, or JavaScript syntax, take a few moments to browse Chapter 2, “Director Scripting Essentials,” on page 9 and Chapter 3, “Writing Scripts in Director,” on page 49 before you begin writing scripts. Like any product, Director has its own unique set of scripting conventions, types of data, and so on. You will need to be comfortable with these unique characteristics of Director before you can write effective scripts.
What’s new with Director scripting

If you have written scripts in previous versions of Director, you should note some new and important changes about scripting in this latest release.

Dot syntax scripting format

In previous releases of Director, you could write Lingo scripts by using two types of syntax: verbose syntax or dot syntax. Verbose syntax was very similar to English, and was relatively easy for new programmers to learn. However, verbose syntax scripts quickly became long and complex, and were difficult to debug.

Now that the scripting model of Director is compatible with both Lingo and JavaScript syntax, scripts should be written only in dot syntax. Dot syntax will be familiar to many programmers, since it is the syntax used in most object-oriented languages such as Java or C++, and in many web-based scripting languages such as Microsoft JScript or JavaScript.

To support backwards compatibility, scripts written by using verbose syntax in previous versions of Director will still run. However, starting with Director MX 2004, dot syntax is the recommended syntax to use, and is the only syntax that will be supported and documented in the future.

For more information on using dot syntax to write scripts, see “Scripting in dot syntax format” on page 50.

JavaScript syntax compatibility

Director is now compatible with JavaScript syntax. This means that in addition to being able to author and debug scripts by using Lingo, which is the long-time scripting language of Director, you can choose to author and debug scripts by using JavaScript syntax. The implementation of JavaScript in Director is referred to as JavaScript syntax throughout this reference.

The support of JavaScript syntax in Director helps create a scripting environment that is familiar not only to JavaScript developers but also to developers experienced with Macromedia Flash ActionScript, Macromedia Flash Communication Server, Macromedia Dreamweaver, Macromedia Authorware, and a number of other environments.

The implementation of JavaScript syntax in Director is JavaScript 1.5, which means that it is fully compliant with the ECMA Script Language Specification ECMA-262, 3rd Edition. Almost all of the features and functionality in JavaScript 1.5 are now available in Director.

For more information on choosing Lingo or JavaScript syntax, see “Choosing between Lingo and JavaScript syntax” on page 49.

Note: This reference is intended to only discuss the features and functionality of the JavaScript 1.5 implementation that are essential to writing JavaScript syntax scripts in Director. It is not intended to provide a complete reference for JavaScript 1.5. For more detailed information on JavaScript 1.5 than is provided in this reference, see one of the many third-party resources on the subject.

New ways to access the scripting APIs

In this release of Director, the scripting APIs have been grouped into objects, and are accessed through these objects. These objects contain the functionality required to add interactivity to your movies and are accessible to both Lingo and JavaScript syntax within Director, projectors, and Macromedia Shockwave Player.
Although the way you access the scripting APIs in this release may vary from previous releases, you still have access to the same APIs that you did before, in addition to some brand new ones. The only difference is that you access them by using the new objects.

For more information on the objects and their corresponding scripting APIs, see “Introducing the Director objects” on page 51.

What’s new in this documentation

If you learned how to script in previous versions of Director, you should know about some changes in the scripting documentation for this release. The Director Scripting Reference takes the place of the Lingo Dictionary that was shipped with previous versions of Director. This reference is organized differently than the Lingo Dictionary.

In the Lingo Dictionary, information about the scripting model was organized by feature. For example, if you wanted to learn how to work with sprites in script, you looked up that information in one of the sections under the Sprites heading, such as Dragging Sprites, Sprite Dimensions, and so on. In addition, all of the scripting APIs were listed in a single alphabetical list, which meant that all functions, properties, events, and so on were mixed together alphabetically.

In the Director Scripting Reference, information about the scripting model is organized by object. This organization closely reflects the organization of the actual scripting objects that you use in your scripts. For example, if you want to find out how to work with sprites in script, you should look for the Sprite section in the chapter, Director Core Objects.

The scripting APIs are still listed in alphabetical order, but they are categorized by API type. For example, all methods are listed alphabetically under the Methods heading, all properties are listed alphabetically under the Properties heading, and so on.

Finding information about scripting in Director

With its new organization, the Director Scripting Reference contains the following topics:

**Director Scripting Essentials** Provides information about the basic scripting concepts and components you will use when scripting in Director.

**Writing Scripts in Director** Provides information about the Director scripting environment in addition to advanced scripting concepts and techniques.

**Debugging Scripts in Director** Provides information about how to find problems in your scripts when they are not performing as expected.

**Director Core Objects** Provides a list of the objects and APIs that you use to access the core functionality and features in Director, such as the Director player engine, movie windows, sprites, sounds, and so on.

**Media Types** Provides a list of the media types and APIs that you use to access the functionality of the various media types in Director, such as RealMedia, DVD, Animated GIF, and so on, that are added to movies as cast members.

**Scripting Objects** Provides a list of the scripting objects, also known as Xtra extensions, and APIs that you use to extend core Director functionality. Xtra extensions provide capabilities such as importing filters and connecting to the Internet.

**3D Objects** Provides a list of the objects you use to add 3D functionality to a movie.
Constants  Provides a list of the constants that are available in Director.
Events and Messages  Provides a list of the events that are available in Director.
Keywords  Provides a list of the keywords that are available in Director.
Methods  Provides a list of the methods that are available in Director.
Operators  Provides a list of the operators that are available in Director.
Properties  Provides a list of the properties that are available in Director.
CHAPTER 2
Director Scripting Essentials

If you are new to scripting in Macromedia Director MX 2004, you may want to take some time to learn the basic scripting concepts that are essential to understanding how to script in Director before you begin. Some of these essentials include definitions of important terms, syntax rules, available data types, and information about the basic elements of scripting in Director—for example, variables, arrays, operators, and so on.

Types of scripts

A Director movie can contain four types of scripts: behaviors, movie scripts, parent scripts, and scripts attached to cast members. Behaviors, movie scripts, and parent scripts all appear as independent cast members in the Cast window. A script attached to a cast member is associated with that cast member in the Cast window and does not appear independently.

• Behaviors are scripts that are attached to sprites or frames in the Score, and are referred to as sprite behaviors or frame behaviors. The Cast window thumbnail for each behavior contains a behavior icon in the lower right corner.

  When used in the Director Scripting Reference, the term behavior refers to any script that you attach to a sprite or a frame. This differs from the behaviors that come in the Director Library Palette. For more information on these behaviors, which are built into Director, see the Using Director topics in the Director Help Panel.

  All behaviors that have been added to a cast library appear in the Behavior inspector’s Behavior pop-up menu. Other types of scripts do not appear there.

  You can attach the same behavior to more than one location in the Score. When you edit a behavior, the edited version is applied everywhere the behavior is attached in the Score.

• Movie scripts contain handlers that are available globally, or on a movie level. Event handlers in a movie script can be called from other scripts in the movie as the movie plays.

  A movie script icon appears in the lower right corner of the movie script’s Cast window thumbnail.

  Movie scripts are available to the entire movie, regardless of which frame the movie is in or which sprites the user is interacting with. When a movie plays in a window or as a linked movie, a movie script is available only to its own movie.
• Parent scripts are special scripts that contain Lingo that is used to create child objects. You can use parent scripts to generate script objects that behave and respond similarly yet can still operate independently of each other. A parent script icon appears in the lower right corner of the Cast window thumbnail.

For information on using parent scripts and child objects, see “Object-oriented programming with Lingo” on page 55.

JavaScript syntax does not use parent scripts or child objects; it uses regular JavaScript syntax-style object-oriented programming techniques. For information on object-oriented programming in JavaScript syntax, see “Object-oriented programming with JavaScript syntax” on page 65.

• Scripts attached to cast members are attached directly to a cast member, independent of the Score. Whenever the cast member is assigned to a sprite, the cast member’s script is available. Unlike behaviors, movie scripts, and parent scripts, cast member scripts do not appear in the Cast window. However, if Show Cast Member Script Icons is selected in the Cast Window Preferences dialog box, cast members that have a script attached display a small script icon in the lower left corner of their thumbnails in the Cast window.

### Scripting terminology

Both Lingo and JavaScript syntax use some terms that are specific to each language, in addition to some terms that are shared between each language.

Important scripting terms are listed here in alphabetical order. These terms are used throughout the Director Scripting Reference, so it will help to understand these terms before moving forward.

• Constants are elements whose values do not change. For example, in Lingo, constants such as TAB, EMPTY, and RETURN always have the same values, and cannot be modified. In JavaScript syntax, constants such as Math.PI and Number.MAX_VALUE always have the same values, and cannot be modified. You can also create your own custom constants in JavaScript syntax by using the keyword `const`.

For more information on constants, see “Constants” on page 20.

• Events are actions that occur while a movie is playing. Events occur when a movie stops, a sprite starts, the playhead enters a frame, the user types at the keyboard, and so on. All events in Director are predefined, and always have the same meaning.

For more information on events, see “Events” on page 33.

• Expressions are any part of a statement that produces a value. For example, `2 + 2` is an expression.

• Functions refer to either top-level functions or specific types of JavaScript syntax code. A top-level function instructs a movie to do something while the movie is playing or returns a value, but it is not called from any specific object. For example, you would call the top-level `list()` function by using the syntax `list()`. Like a function, a method also instructs a movie to do something while the movie is playing or returns a value, but it is always called from an object.

A function is used in JavaScript syntax to represent an event handler, a custom object, a custom method, and so on. The use of JavaScript functions in these cases is described in the applicable topics later in this reference.
• Handlers, or event handlers, are sets of statements within a script that run in response to a specific event and subsequent message. When an event occurs, Director generates and sends a corresponding message to scripts, and a corresponding handler runs in response to the message. The names of handlers are always the same as the events and messages they respond to.

Note: Although in JavaScript syntax an event is actually handled by a function, the term handler is used generically throughout this reference to refer to both Lingo handlers and JavaScript syntax functions that handle events.

For more information on handlers, see “Handlers” on page 35.

• Keywords are reserved words that have a special meaning. For example, in Lingo, the keyword end indicates the end of a handler. In JavaScript syntax, the keyword var indicates that the term following it is a variable.

• Lists (Lingo) or Arrays (JavaScript syntax) are ordered sets of values used to track and update an array of data, such as a series of names or the values assigned to a set of variables. A simple example is a list of numbers such as [1, 4, 2].

For more information on using lists in both Lingo and JavaScript syntax, see "Linear lists and property lists" on page 38.

For more information on using JavaScript syntax arrays, see "JavaScript syntax arrays" on page 45.

• Messages are notices that Director sends to scripts when specific events occur in a movie. For example, when the playhead enters a specific frame, the enterFrame event occurs and Directors sends an enterFrame message. If a script contains an enterFrame handler, the statements within that handler will run, because the handler received the enterFrame message. If no scripts contain a handler for a message, the message is ignored in script.

For more information on messages, see “Messages” on page 34.

• Methods are terms that either instruct a movie to do something while the movie is playing or return a value, and are called from an object. For example, you would call the insertFrame() method from the Movie object, using the syntax _movie.insertFrame(). Although similar in functionality to top-level functions, methods are always called from an object, and top-level functions are not.

• Operators are terms that calculate a new value from one or more values. For example, the addition (+) operator adds two or more values together to produce a new value.

For more information on operators, see “Operators” on page 25.

• Parameters are placeholders that let you pass values to scripts. Parameters only apply to methods and event handlers, and not to properties. They are required by some methods and optional for others.

For example, the Movie object’s go() method sends the playhead to specific frame, and optionally specifies the name of the movie that frame is in. To perform this task, the go() method requires at least one parameter, and allows for a second parameter. The first required parameter specifies what frame to send the playhead to, and the second optional parameter specifies what movie the frame is in. Because the first parameter is required, a script error will result if it is not present when the go() method is called. Because the second parameter is optional, the method will perform its task even if the parameter is not present.
• Properties are attributes that define an object. For example, a sprite in a movie has specific attributes, such as how wide it is, how tall it is, its background color, and so on. To access the values of these three specific attributes, you would use the Sprite object's `width`, `height`, and `backColor` properties.

   For more information on assigning properties to variables, see “Storing and updating values in variables” on page 21.

• Statements are valid instructions that Director can execute. All scripts are made up of sets of statements. The following Lingo is a single complete statement.

```lingo
_movie.go("Author")
```

   For more information on writing script statements, see “Scripting in dot syntax format” on page 50

• Variables are elements used to store and update values. Variables must start with a letter, an underscore (\_), or the dollar sign ($). Subsequent characters in a variable name can also be digits (0-9). To assign values to variables or change the values of many properties, you use the `=` operator.

   For more information on using variables, see "Variables" on page 21.

### Scripting syntax

The following are general syntax rules that apply to Lingo and JavaScript syntax.

• Comment markers vary between Lingo and JavaScript syntax.

   All Lingo comments are preceded by double hyphens (``--``). Each line of a comment that covers multiple lines must be preceded by double hyphens.

   ```lingo
   -- This is a single-line Lingo comment
   -- This is a multiple-line Lingo comment
   ```

   JavaScript syntax comments on a single line are preceded by a double-slash (`//`). Comments that cover multiple lines are preceded with a `/*` and followed by a `*/`.

   ```javascript
   // This is a single-line JavaScript syntax comment
   /* This is a multiple-line JavaScript syntax comment */
   ```

   You can place a comment on its own line or after any statement. Any text following the comment markers on the same line are ignored.

   Comments can consist of anything you want, such as notes about a particular script or handler or notes about a statement whose purpose might not be obvious. Comments make it easier for you or someone else to understand a procedure after you’ve been away from it for a while.

   Adding large numbers of comments does not increase the size of your movie file when it is saved as a compressed DCR or DXR file. Comments are removed from the file during the compression process.

   Comment markers can also be used to ignore sections of code you want to deactivate for testing or debugging purposes. By adding comment markers rather than removing the code, you can temporarily turn it into comments. Select the code you want to turn on or off, and then use the Comment or Uncomment buttons in the Script window to quickly add or remove comment markers.
• Parentheses are required after all method and function names. For example, when calling the Sound object's beep() method, you must include the parentheses after the word beep. Otherwise, a script error will occur.

```javascript
// JavaScript syntax
_sound.beep(); // this statement will work properly
_sound.beep; // this statement will result in a script error
```

When you call a method, function, or handler from within another method, function, or handler, you must include parentheses in the calling statement. In the following example, the modifySprite() method contains a call to a spriteClicked handler. The call to the spriteClicked handler must include parentheses; otherwise, a script error occurs.

```javascript
function modifySprite() {
  spriteClicked(); // this call to the handler will work properly
  spriteClicked; // this call to the handler results in a script error
}
function spriteClicked() {
  // handler code here
}
```

You can also use parentheses to override the order of precedence in math operations, or to make your statements easier to read. For example, the first math expression below yields a result of 13, while the second expression yields a result of 5:

```
5 * 3 - 2 -- yields 13
5 * (3 - 2) -- yields 5
```

• Event handler syntax varies between Lingo and JavaScript syntax. In Lingo, handlers use the syntax `on handlerName`. In JavaScript syntax, handlers are implemented as functions, and use the syntax `function handlerName()`. For example, the following statements comprise a handler that plays a beep when the mouse button is clicked:

```lingo
-- Lingo syntax
on mouseDown
  _sound.beep()
end
```

```javascript
// JavaScript syntax
function mouseDown() {
  _sound.beep();
}
```

• Event handler parameter syntax can vary between Lingo and JavaScript syntax. Both Lingo and JavaScript syntax support enclosing parameters passed to a handler within parentheses. If more than one parameter is passed, each parameter is separated by a comma. In Lingo, you can also pass parameters that are not enclosed by parentheses. For example, the following addThem handler receives the two parameters a and b.

```lingo
-- Lingo syntax
on addThem a, b -- without parentheses
  c = a + b
end
on addThem(a, b) -- with parentheses
  c = a + b
end
```

```javascript
// JavaScript syntax
function addThem(a, b) {
  c = a + b;
}
```
The `const` keyword can be used in JavaScript syntax to specify a constant whose value does not change. Lingo has its own predefined set of constants (TAB, EMPTY, and so on); therefore, the keyword `const` does not apply to Lingo.

For example, the following statement specifies a constant named `intAuthors` and sets its value to 12. This value will always be 12, and cannot be changed through script.

```javascript
// JavaScript syntax
const intAuthors = 12;
```

The `var` keyword in JavaScript syntax can be placed in front of a term to specify that the term is a variable. The following statement creates a variable named `startValue`.

```javascript
// JavaScript syntax
var startValue = 0;
```

**Note:** Although using `var` in JavaScript syntax is optional, it is recommended that you always declare local JavaScript syntax variables, or those inside a function, using `var`. For more information on using variables, see "Variables" on page 21.

The line continuation symbol (\) in Lingo indicates that a long line of sample code has been broken into two or more lines. Lines of Lingo that are broken in this way are not separate lines of code. For example, the following code would still run.

```lingo
-- Lingo syntax
tTexture = member("3D").model("box")
   .shader.texture
```

JavaScript syntax does not include a line continuation symbol. To break multiple lines of JavaScript syntax code, add a carriage return at the end of a line, and then continue the code on the following line.

Semicolons can be used to specify the end of a statement of JavaScript syntax code. Semicolons do not apply to Lingo.

Using a semicolon is optional. If used, it is placed at the end of a complete statement. For example, both of the following statements create a variable named `startValue`.

```javascript
// JavaScript syntax
var startValue = 0
var startValue = 0;
```

A semicolon does not necessarily specify the end of a line of JavaScript syntax code, and multiple statements can be placed on one line. However, placing separate statements on separate lines is recommended in order to improve readability. For example, the following three statements occupy only one line of code and function properly, but it is difficult to read the code.

```javascript
// JavaScript syntax
_movie.go("Author"); var startValue = 0; _sound.beep();
```

Character spaces within expressions and statements are ignored in both Lingo and JavaScript syntax. In strings of characters surrounded by quotation marks, spaces are treated as characters. If you want spaces in a string, you must insert them explicitly. For example, the first statement below ignores the spaces between the list items, and the second statement includes the spaces.

```lingo
-- Lingo syntax
myList1 = ["1", "2", "3"] -- yields ["1", "2", "3"]
myList2 = ["  1  ", "  2  ", "  3  "] -- yields ["  1  ", "  2  ", "  3  "]
```
• Case-sensitivity can vary between Lingo and JavaScript syntax.

Lingo is not case-sensitive in any circumstance—you can use uppercase and lowercase letters however you want. For example, the following four statements are equivalent:

```
-- Lingo syntax
member("Cat").hilite = true
member("cat").hilite = True
MEMBER("CAT").HILITE = TRUE
Member("Cat").Hilite = true
```

Although Lingo is not case-sensitive, it’s a good habit to choose a case convention and use it consistently throughout your scripts. This makes it is easier to identify names of handlers, variables, cast members, and so on.

JavaScript syntax is case-sensitive when referring to objects, the top level properties or methods that refer to objects, or when referring to user-defined variables. For example, the top level `sprite()` method returns a reference to a specific Sprite object, and is implemented in Director with all lowercase letters. The first statement below refers to the name of the first sprite in a movie, while the second and third statements result in a script error.

```
// JavaScript syntax
sprite(1).name // This statement functions normally
Sprite(1).name // This statement results in a script error
SPRITE(1).name // This statement results in a script error
```

Literal strings are always case-sensitive in both Lingo and JavaScript syntax.

For more information on using strings, see "Strings" on page 18.

**Data types**

A data type is a set of data with values that have similar, predefined characteristics. Every variable and property value in Director is of a specific data type, and values returned by methods are of a specific data type.

For example, consider the following two statements. In the first statement, variable `intX` is assigned a whole number value of 14, which is an integer. So, the data type of variable `intX` is integer. In the second statement, variable `stringX` is assigned a sequence of character values, which is a string. So, the data type of variable `stringX` is string.

```
-- Lingo syntax
intX = 14
stringX = "News Headlines"

// JavaScript syntax
var intX = 14;
var stringX = "News Headlines";
```

The values that are returned by methods or functions are also of an inherent data type. For example, the Player object’s `windowPresent()` method returns a value that specifies whether a window is present. The returned value is `TRUE` (1) or `FALSE` (0).
Some data types are shared between Lingo and JavaScript syntax, and some data types are specific to one language or another. The set of data types that Director supports is fixed and cannot be modified, meaning that new data types cannot be added and existing data types cannot be removed. Director supports the following data types.

<table>
<thead>
<tr>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td># (symbol)</td>
<td>A self-contained unit that can be used to represent a condition or flag. For example, #list or #word.</td>
</tr>
<tr>
<td>Array</td>
<td>(JavaScript syntax only) Although not literally a data type, an Array object can be used to work with linear lists of values. The functionality of an Array object is similar to that of the List data type in Lingo.</td>
</tr>
<tr>
<td>Boolean</td>
<td>A value that is TRUE (1) or FALSE (0). In Lingo, all TRUE or FALSE values are simple integer constants. 1 for TRUE, 0 for FALSE. In JavaScript syntax, all true or false values are by default the actual Boolean true or false values, but are converted to simple integer constants automatically when required in Director. In Lingo, TRUE and FALSE can be either lowercase or uppercase. In JavaScript syntax, true and false must always be lowercase.</td>
</tr>
<tr>
<td>Color</td>
<td>Represents an object's color.</td>
</tr>
<tr>
<td>Constant</td>
<td>A piece of data whose value does not change.</td>
</tr>
<tr>
<td>Date</td>
<td>Although not literally a data type, in JavaScript syntax a Date object can be used to work with dates. In Lingo, use the date() method to create a Date object and work with dates.</td>
</tr>
<tr>
<td>Float</td>
<td>(Lingo only) A floating-point number. For example, 2.345 or 45.43.</td>
</tr>
<tr>
<td>Function</td>
<td>(JavaScript syntax only) Although not literally a data type, a Function object can be used to specify a string of code to run.</td>
</tr>
<tr>
<td>Integer</td>
<td>(Lingo only) A whole number. For example, 5 or 298.</td>
</tr>
<tr>
<td>List</td>
<td>A linear or property list made up of values or property names and values, respectively.</td>
</tr>
<tr>
<td>Math</td>
<td>(JavaScript syntax only) Although not literally a data type, a Math object can be used to perform mathematical functions.</td>

<td>(JavaScript only) A regular expression pattern that is used to match character combinations in strings.</td>
</tr>
<tr>
<td>String</td>
<td>A contiguous sequence of keyboard symbols or character values. For example, &quot;Director&quot; or &quot;$5.00&quot;.</td>
</tr>
</tbody>
</table>
Many of the data types and objects that are specific to JavaScript syntax contain their own set of methods and properties that can be used to further manipulate those types. While the Director Scripting Reference may refer to some of these methods and properties, it does not include complete reference information about them. For more detailed information on these data types and objects, and their methods and properties, see one of the many third-party resources on the subject.

The built-in properties in Director, such as the Cast object's `name` property, can only be assigned values that are the same data type as that of the property's inherent data type. For example, the Cast object's `name` property's inherent data type is a string, so the value must be a string such as "News Headlines." If you try to assign a value of a different data type to this property, such as the integer 20, a script error occurs.

If you create your own custom properties, their values can be of any data type, regardless of the data type of the initial value.

Both Lingo and JavaScript syntax are dynamically typed. This means that you do not have to specify the data type of a variable when you declare it, and data types are automatically converted as needed while a script runs.

For example, the following JavaScript syntax initially sets the variable `myMovie` to an integer, and later in the script it is set to a string. When the script runs, the data type of `myMovie` is converted automatically.

```javascript
// JavaScript syntax
var myMovie = 15; // myMovie is initially set to an integer

myMovie = "Animations"; // myMovie is later set to a string
```

<table>
<thead>
<tr>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>undefined</td>
<td>(JavaScript syntax only) Denotes a variable that does not have a value.</td>
</tr>
<tr>
<td>Vector</td>
<td>A point in 3D space.</td>
</tr>
<tr>
<td>VOID</td>
<td>(Lingo only) Denotes an empty value.</td>
</tr>
</tbody>
</table>

Note: Many of the data types and objects that are specific to JavaScript syntax contain their own set of methods and properties that can be used to further manipulate those types. While the Director Scripting Reference may refer to some of these methods and properties, it does not include complete reference information about them. For more detailed information on these data types and objects, and their methods and properties, see one of the many third-party resources on the subject.
Literal values

A literal value is any part of a statement or expression that is to be used exactly as it is, rather than as a variable or a script element. Literal values that you encounter in script are character strings, integers, decimal numbers, cast member names and numbers, frame and movie names and numbers, symbols, and constants.

Each type of literal value has its own rules.

Strings

Strings are words or groups of characters that script treats as regular words instead of as variables. Strings must be enclosed in double quotation marks. For example, you might use strings to give messages to the user of your movie or to name cast members. In the following statement, Hello and Greeting are both strings. Hello is the literal text being put into the text cast member; Greeting is the name of the cast member:

```-- Lingo syntax
member("Greeting").text = "Hello"
```

Similarly, if you test a string, double quotation marks must surround each string, as in the following example:

```-- Lingo syntax
if "Hello Mr. Jones" contains "Hello" then soundHandler
```

Both Lingo and JavaScript syntax treat spaces at the beginning or end of a string as a literal part of the string. The following expression includes a space after the word to:

```// JavaScript syntax
trace("My thoughts amount to ");
```

Although Lingo does not distinguish between uppercase and lowercase when referring to cast members, variables, and so on, literal strings are case-sensitive. For example, the following two statements place different text into the specified cast member, because Hello and HELLO are literal strings:

```-- Lingo syntax
member("Greeting").text = "Hello"
member("Greeting").text = "HELLO"
```

In Lingo, the `string()` function can convert a numerical value into a string. In JavaScript syntax, the `toString()` method can convert a numerical value into a string.

Note: Attempting to use the `toString()` method in JavaScript syntax on a null or undefined value results in a script error. This is in contrast with Lingo, in which the `string()` function works on all values, including those that are VOID.

Numbers

In Lingo, there are two types of numbers: integers and decimals.

An integer is a whole number, without any fractions or decimal places, in the range of -2,147,483,648 and +2,147,483,647. Enter integers without using commas. Use a minus (-) sign for negative numbers.
A decimal number, also called a floating-point number, or float, is any number that includes a decimal point. In Lingo, the floatPrecision property controls the number of decimal places used to display these numbers. Director always uses the complete number, up to 15 significant digits, in calculations; Director rounds any number with more than 15 significant digits in calculations.

JavaScript syntax does not distinguish between integers and floating-point numbers, and merely uses numbers. For example, the following statements illustrate that the number 1 is an integer in Lingo and a number in JavaScript syntax, and that the decimal number 1.05 is a float in Lingo and a number in JavaScript syntax:

-- Lingo syntax
put(ilk(1)) -- #integer
put(ilk(1.05)) -- #float

// JavaScript syntax
trace(typeof(1)) // number
trace(typeof(1.05)) // number

In Lingo, you can convert a decimal to an integer by using the integer() function. You can also convert an integer to a decimal by performing a mathematical operation on the integer, for example, by multiplying an integer by a decimal. In JavaScript syntax, you can convert a string or a decimal number to a whole number by using the parseInt() function. As opposed to Lingo's integer() function, parseInt() rounds down. For example, the following statement rounds off the decimal number 3.9 and converts it to the integer 4 (Lingo) and the number 3 (JavaScript syntax).

-- Lingo syntax
theNumber = integer(3.9) -- results in a value of 4

// JavaScript syntax
var theNumber = parseInt(3.9); // results in a value of 3

In Lingo, the value() function can convert a string into a numerical value.

You can also use exponential notation with decimal numbers: for example, -1.1234e-100 or 123.4e+9.

In Lingo, you can convert an integer or string to a decimal number by using the float() function. In JavaScript syntax, you can convert a string to a decimal number by using the parseFloat() function. For example, the following statement stores the value 3.0000 (Lingo) and 3 (JavaScript syntax) in the variable theNumber.

-- Lingo syntax
theNumber = float(3) -- results in a value of 3.0000

// JavaScript syntax
var theNumber = parseFloat(3) // results in a value of 3
Constants

A constant is a named value whose content never changes.

In Lingo, the predefined terms TRUE, FALSE, VOID, and EMPTY are constants because their values are always the same. The predefined terms BACKSPACE, ENTER, QUOTE, RETURN, SPACE, and TAB are constants that refer to keyboard characters. For example, to test whether the last key pressed was the Space bar, use the following statement:

```lingo
-- Lingo syntax
if _key.keyPressed() = SPACE then beep()
```

In JavaScript syntax, you can access predefined constants using some of the data types that are unique to JavaScript syntax. For example, the Number object contains constants such as Number.MAX_VALUE and Number.NaN, the Math object contains constants such as Math.PI and Math.E, and so on.

*Note:* This reference does not provide in-depth information about the predefined constants in JavaScript syntax. For more information on these constants, see one of the many third-party resources on the subject.

In JavaScript syntax, you can also define your own custom constants by using the `const` keyword. For example, the following statement creates a constant named `items`, and assigns it a value of 20. This value cannot be changed after it has been created.

```javascript
// JavaScript syntax
const items = 20;
```

For more information on constants, see Chapter 9, “Constants,” on page 151.

Symbols

A symbol is a string or other value in Lingo that begins with the pound (#) sign.

Symbols are user-defined constants. Comparisons using symbols can usually be performed very quickly, providing more efficient code.

For example, the first statement below runs more quickly than the second statement:

```lingo
-- Lingo syntax
userLevel = #novice
userLevel = "novice"
```

Symbols cannot contain spaces or punctuation.

In both Lingo and JavaScript syntax, convert a string to a symbol by using the `symbol()` method.

```lingo
-- Lingo syntax
x = symbol("novice") -- results in #novice
```

```javascript
// JavaScript syntax
var x = symbol("novice"); // results in #novice
```

Convert a symbol back to a string by using the `string()` function (Lingo) or the `toString()` method (JavaScript syntax).

```lingo
-- Lingo syntax
x = string(#novice) -- results in "novice"
```

```javascript
// JavaScript syntax
var x = symbol("novice").toString(); // results in "novice"
```
In JavaScript syntax, you cannot compare symbols of the same name to determine whether they refer to the same symbol. To compare symbols of the same name, you must first convert them to strings by using the `toString()` method, and then perform the comparison.

**Variables**

Director uses variables to store and update values. As the name implies, a variable contains a value that can be changed or updated as a movie plays. By changing the value of a variable as the movie plays, you can do things such as store a URL, track the number of times a user takes part in an online chat session, record whether a network operation is complete, and many more options.

It is a good idea always to assign a variable a known value the first time you declare the variable. This is known as initializing a variable. Initializing variables makes it easier to track and compare the variable's value as the movie plays.

Variables can be global or local. A local variable exists only as long as the handler in which it is defined is running. A global variable can exist and retain its value as long as Director is running, including when a movie branches to another movie. A variable can be global within an individual handler, a specific script, or an entire movie; the scope depends on how the global variable is initialized.

If you want a variable to be available throughout a movie, it is good practice to declare it in an `on prepareMovie` (Lingo) or a function `prepareMovie()` (JavaScript syntax) handler. This ensures that the variable is available from the very start of the movie.

For more information on using both global and local variables, see “Using global variables” on page 22 and “Using local variables” on page 24.

**Storing and updating values in variables**

Variables can hold data for any of the data types found in Director, such as integers, strings, `TRUE` or `FALSE` values, symbols, lists, or the result of a calculation. Use the equals (=) operator to store the values of properties and variables.

As mentioned in the Data types section of this reference, variables in both Lingo and JavaScript syntax are dynamically typed, which means that they can contain different types of data at different times. (The ability to change a variable's type distinguishes Lingo from other languages such as Java and C++, in which a variable's type cannot be changed.)

For example, the statement `x = 1` creates the variable `x`, which is an integer variable because you assigned the variable an integer. If you subsequently use the statement `x = "one"`, the variable `x` becomes a string variable, because the variable now contains a string.

You can convert a string to a number by using the `value()` function (Lingo) or the `parseInt()` method (JavaScript syntax), or a number to a string by using the `string()` function (Lingo) or the `toString()` method (JavaScript syntax).

The values of some properties can be both set (the value is assigned) and returned (the value is retrieved), and some property values can only be returned. Properties whose values can be both set and returned are called read/write, and those that can only be returned are called read-only.

Often these are properties that describe some condition that exists outside the control of Director. For example, you cannot set the `numChannels` cast member property, which indicates the number of channels within a movie that contains Macromedia Shockwave content. However, you can return the number of channels by referring to the `numChannels` property of a cast member.
To assign a value to a variable:

- Use the equals (=) operator.

For example, the following statement assigns a URL to the variable placesToGo:

```
// JavaScript syntax
var placesToGo = "http://www.macromedia.com";
```

Variables can also hold the results of mathematical operations. For example, the following statement adds the result of an addition operation to the variable mySum:

```
-- Lingo syntax
mySum = 5 + 5  -- this sets mySum equal to 10
```

As another example, the following statement returns the cast member assigned to sprite 2 by retrieving the value of the sprite's member property and places it into the variable textMember.

```
-- Lingo syntax
textMember = sprite(2).member
```

It is good practice to use variable names that indicate what the variable is used for. This makes your scripts easier to read. For example, the variable mySum indicates that the variable contains a sum of numbers.

To test the values of properties or variables:

- Use the put() or the trace() functions in the Message window or check the values in the Watcher window; (put() and trace() provide identical functionality and are available to both Lingo and JavaScript syntax).

For example, the following statement displays the value assigned to the variable myNumber in the Message window.

```
-- Lingo syntax
myNumber = 20 * 7
put(myNumber)  -- displays 140 in the Message window
```

```
// JavaScript syntax
var myNumber = 20 * 7;
trace(myNumber)  // displays 140 in the Message window
```

Using global variables

Global variables can be shared among handlers, scripts, or movies. A global variable exists and retains its value as long as Director is running or until you call the clearGlobals() method.

In Macromedia Shockwave Player, global variables persist among movies displayed by the goToNetMovie() method, but not among those displayed by the goToNetPage() method.

Every handler that declares a variable as global can use the variable’s current value. If the handler changes the variable’s value, the new value is available to every other handler that treats the variable as global.

It is good practice to start the names of all global variables with a lowercase g. This helps identify which variables are global when you examine your code.

Director provides a way to display all current global variables and their current values and to clear the values of all global variables.
To display all current global variables and their current values:

- Use the Global object's `showGlobals()` method in the Message window.

For more information on the Message window, see “Debugging in the Message window” on page 87.

To clear all current global variables:

- Use the Global object's `clearGlobals()` method in the Message window to set the value of all global variables to `VOID` (Lingo) or `undefined` (JavaScript syntax).

To monitor the values of global variables during movie playback, use the Object inspector. For more information on the Object inspector, see “Debugging in the Object inspector” on page 91.

**Global variables in Lingo**

In Lingo, variables are considered local by default, and you do not need to precede the variable name with any keyword. To declare a global variable, you must precede the variable with the keyword `global`.

If you declare a global variable at the top of a script and before any handlers, the variable is available to all handlers in that specific script. If you declare a global variable within a handler, the variable is available only to that handler; however, if you declare a global variable with the same name within two separate handlers, an update to the variable's value in one handler will also be reflected in the variable in the other handler.

The following example illustrates working with two global variables: `gScript`, which is available to all handlers in the script, and `gHandler`, which is available within its defining handler and any other handlers that declare it on the first line of the handler.

```
-- Lingo syntax
global gScript -- gScript is available to all handlers

on mouseDown
    global gHandler
    gScript = 25
    gHandler = 30
end

on mouseUp
    global gHandler
    trace(gHandler) -- displays 30
end
```

In Lingo, when you use the term `global` to define global variables, the variables automatically have `VOID` as their initial value.

**Global variables in JavaScript syntax**

In JavaScript syntax, variables are considered global by default. The scope of a global variable can be determined by how and where it is declared.

- If you declare a variable within a JavaScript syntax function without preceding the variable name with the keyword `var`, the variable is available to all functions within its containing script.
- If you declare a variable outside a JavaScript syntax function, with or without the keyword `var`, the variable is available to all functions within its containing script.
• If you declare a variable inside or outside a JavaScript syntax function by using the syntax
   _global.varName, the variable is available to all scripts within a movie.

The following example uses the syntax _global.gMovie in one script to declare the variable
gMovie as global. This variable is available to all scripts within the movie.

   // JavaScript syntax
   _global.gMovie = 1; // Declare gMovie in one script
   // Create a function in a separate script that operates on gMovie
   function mouseDown() {
     _global.gMovie++;
     return(_global.gMovie);
   }

The following example declares the global variable gScript in one script. This variable is
available only to functions within that script.

   // JavaScript syntax
   var gScript = 1; // Declare gScript in a script
   // gScript is available only to functions in the script that defines it
   function mouseDown() {
     gScript++;
     return(gScript);
   }

In JavaScript syntax, when you define variables before any handlers, the variables automatically
have undefined as their initial value.

Using local variables

A local variable exists only as long as the handler in which it is defined is running. However, after
a local variable is created, you can use the variable in other expressions or change its value while a
script is still within the handler that defined the variable.

Treating variables as local is a good idea when you want to use a variable only temporarily in one
handler. This helps you avoid unintentionally changing the value in another handler that uses the
same variable name.

To create a local variable:

• In Lingo, assign the variable a value using the equals (=) operator.
• In JavaScript syntax, inside a function precede the variable name with the keyword var, and
  then assign the variable a value using the equals operator.
  
  Note: Because JavaScript syntax variables are global by default, if you attempt to declare a local
  variable inside a function without using the keyword var, your script could produce unexpected
  behavior. Therefore, although using var is optional, it is strongly recommended that you declare all
  local JavaScript syntax variables using var to avoid any unexpected behavior.

To display all current local variables in the handler:

• In Lingo only, use the showLocals() function.

In Lingo, you can use this method in the Message window or in handlers to help with debugging.
The result appears in the Message window. The showLocals() method does not apply to
JavaScript syntax.

To monitor the values of local variables during movie playback, use the Object inspector. For
more information on the Object inspector, see “Debugging in the Object inspector” on page 91.
Operators

Operators are elements that tell Lingo and JavaScript syntax scripts how to combine, compare, or modify the values of an expression. Many of the operators in Director are shared between Lingo and JavaScript syntax, and some are unique to each language.

Some types of operators include the following:

- Arithmetic operators (such as +, -, /, and *)
- Comparison operators (such as <, >, and >=), which compare two arguments
- Logical operators (not, and, or), which combine simple conditions into compound ones
- String operators (such as &, &&, and +), which join, or concatenate, strings of characters

Note: There are many more types of operators in JavaScript syntax than there are in Lingo, and not all of them are covered in this reference. For more information on additional operators in JavaScript 1.5, see one of the many third-party resources on the subject.

The items that operators act upon are called operands. In Lingo, there are only binary operators. In JavaScript syntax, there are both binary and unary operators. A binary operator requires two operands, one before the operator and one after the operator. A unary operator requires a single operand, either before or after the operator.

In the following example, the first statement illustrates a binary operator, where the variables x and y are operands and the plus (+) sign is the operator. The second statement illustrates a unary operator, where the variable i is the operand and ++ is the operator.

```
// JavaScript syntax
x + y; // binary operator
i++; // unary operator
```

For reference information on operators, see Chapter 13, “Operators,” on page 591.

Understanding operator precedence

When two or more operators are used in the same statement, some operators take precedence over others in a precise hierarchy to determine which operators to execute first. This is called the operators’ precedence order. For example, multiplication is always performed before addition. However, items in parentheses take precedence over multiplication. In the following example, without parentheses the multiplication in this statement occurs first:

```
-- Lingo syntax
total = 2 + 4 * 3 -- results in a value of 14
```

When parentheses surround the addition operation, addition occurs first:

```
-- Lingo syntax
total = (2 + 4) * 3 -- results in a value of 18
```

Descriptions of the types of operators and their precedence order follow. Operators with higher precedence are performed first. For example, an operator whose precedence order is 5 is performed before an operator whose precedence order is 4. Operations that have the same order of precedence are performed left to right.
Arithmetic operators

Arithmetic operators add, subtract, multiply, divide, and perform other arithmetic operations. Parentheses and the minus sign are also arithmetic operators.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Effect</th>
<th>Precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>(</td>
<td>Groups operations to control precedence order.</td>
<td>5</td>
</tr>
<tr>
<td>-</td>
<td>When placed before a number, reverses the sign of a number.</td>
<td>5</td>
</tr>
<tr>
<td>*</td>
<td>Performs multiplication.</td>
<td>4</td>
</tr>
<tr>
<td>mod</td>
<td>(Lingo only) Performs modulo operation.</td>
<td>4</td>
</tr>
<tr>
<td>/</td>
<td>Performs division.</td>
<td>4</td>
</tr>
<tr>
<td>%</td>
<td>(JavaScript syntax only) Returns the integer remainder of dividing two operands.</td>
<td>4</td>
</tr>
<tr>
<td>++</td>
<td>(JavaScript syntax only) Adds one to its operand. If used as a prefix operator (++x), returns the value of its operand after adding one. If used as a postfix operator (x++), returns the value of its operand before adding one.</td>
<td>4</td>
</tr>
<tr>
<td>--</td>
<td>(JavaScript syntax only) Subtracts one from its operand. The return value is analogous to that of the increment operator.</td>
<td>4</td>
</tr>
<tr>
<td>+</td>
<td>When placed between two numbers, performs addition.</td>
<td>3</td>
</tr>
<tr>
<td>-</td>
<td>When placed between two numbers, performs subtraction.</td>
<td>3</td>
</tr>
</tbody>
</table>

Note: In Lingo, when only integers are used in an operation, the result is an integer. Using integers and floating-point numbers in the same calculation results in a floating-point number. In JavaScript syntax, all calculations essentially result in floating-point numbers.

When dividing one integer by another does not result in a whole number, Lingo rounds the result down to the nearest integer. For example, the result of 4/3 is 1. In JavaScript syntax, the actual floating-point value, 1.333, is returned.

To force Lingo to calculate a value without rounding the result, use `float()` on one or more values in an expression. For example, the result of 4/float(3) is 1.333.

Comparison operators

Comparison operators compare two values and determine whether the comparison is true or false.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
<th>Precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>==</td>
<td>(JavaScript syntax only) Two operands are equal. If the operands are not of the same data type, JavaScript syntax attempts to convert the operands to an appropriate data type for the comparison.</td>
<td>1</td>
</tr>
<tr>
<td>===</td>
<td>(JavaScript syntax only) Two operands are equal and of the same data type</td>
<td>1</td>
</tr>
<tr>
<td>!=</td>
<td>(JavaScript syntax only) Two operands are not equal. If the operands are not of the same data type, JavaScript syntax attempts to convert the operands to an appropriate data type for the comparison.</td>
<td>1</td>
</tr>
</tbody>
</table>
Assignment operators

Assignment operators assign a value to its left operand based on the value of its right operand. With the exception of the basic assignment operator, equal (=), all of the following shortcut assignment operators apply only to JavaScript syntax.

### Assignment operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
<th>Precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Equal</td>
<td>1</td>
</tr>
<tr>
<td>x += y</td>
<td>(JavaScript syntax only) ( x = x + y )</td>
<td>1</td>
</tr>
<tr>
<td>x -= y</td>
<td>(JavaScript syntax only) ( x = x - y )</td>
<td>1</td>
</tr>
<tr>
<td>x *= y</td>
<td>(JavaScript syntax only) ( x = x \times y )</td>
<td>1</td>
</tr>
<tr>
<td>x /= y</td>
<td>(JavaScript syntax only) ( x = x / y )</td>
<td>1</td>
</tr>
<tr>
<td>x %= y</td>
<td>(JavaScript syntax only) ( x = x % y )</td>
<td>1</td>
</tr>
</tbody>
</table>

Logical operators

Logical operators test whether two logical expressions are true or false.

Use care when using logical operators and string operators in Lingo and JavaScript syntax. For example, in JavaScript syntax `&&` is a logical operator that determines whether both expressions are true, but in Lingo, `&&` is a string operator that concatenates two strings and inserts a space between the two expressions.

### Logical operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Effect</th>
<th>Precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>and</td>
<td>(Lingo only) Determines whether both expressions are true</td>
<td>4</td>
</tr>
<tr>
<td>&amp;&amp;</td>
<td>(JavaScript syntax only) Determines whether both expressions are true</td>
<td>4</td>
</tr>
<tr>
<td>or</td>
<td>(Lingo only) Determines whether either or both expressions are true</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>not</td>
<td>(Lingo only) Negates an expression</td>
<td>5</td>
</tr>
<tr>
<td>!</td>
<td>(JavaScript syntax only) Negates an expression</td>
<td>5</td>
</tr>
</tbody>
</table>
The `not` (Lingo) or `!` (JavaScript syntax) operator is useful for toggling a **TRUE** or **FALSE** value to its opposite. For example, the following statement turns on the sound if it's currently off and turns off the sound if it's currently on:

```
-- Lingo syntax
_sound.soundEnabled = not (_sound.soundEnabled)

// JavaScript syntax
_sound.soundEnabled = !_sound.soundEnabled;
```

### String operators

String operators combine and define strings.

Use care when using logical operators and string operators in Lingo and JavaScript syntax. For example, in JavaScript syntax `&&` is a logical operator that determines whether two expressions are true, but in Lingo, `&&` is a string operator that concatenates two strings and inserts a space between the two expressions.

### Conditional constructs

By default, Director always executes script statements starting with the first statement and continuing in order until it reaches the final statement or a statement that instructs a script to go somewhere else.

The order in which statements are executed affects the order in which you should place statements. For example, if you write a statement that requires some calculated value, you need to put the statement that calculates the value first.

The first statement in the following example adds two numbers, and the second statement assigns a string representation of the sum to a field cast member named `Answer`, which appears on the Stage. The second statement could not be placed before the first statement because the variable `x` has not yet been defined.

```
-- Lingo syntax
x = 2 + 2
member("Answer").text = string(x)

// JavaScript syntax
var x = 2 + 2;
member("Answer").text = x.toString();
```
Both Lingo and JavaScript syntax provide conventions for altering the default execution order or script statements, and for performing actions depending on specific conditions. For example, you may want to do the following in your scripts:

- Execute a set of statements if a logical condition is true, or execute alternate statements if the logical condition is false.
- Evaluate an expression and attempt to match the expression's value to a specific condition.
- Execute a set of statements repeatedly until a specific condition is met.

**Testing for logical conditions**

To execute a statement or set of statements if a specified condition is true or false, you use the `if...then...else` (Lingo) or `if...else` (JavaScript syntax) structures. For example, you can create an `if...then...else` structure that tests whether text has finished downloading from the Internet and, if it has, then attempts to format the text. These structures use the following pattern to test for logical conditions:

- In both Lingo and JavaScript syntax, statements that check whether a condition is true or false begin with the term `if`.
- In Lingo, if the condition exists, the statements following the term `then` are executed. In JavaScript syntax, curly brackets (`{ }`) take the place of the Lingo term `then`, and must surround each individual `if`, `else`, or `else if` statement.
- In both Lingo and JavaScript syntax, if the condition does not exist, scripts skip to the next statement in the handler using the term `else` or `else if`.
- In Lingo, the term `end if` specifies the end of the `if` test. In JavaScript syntax, the `if` test ends automatically, so there is no term that explicitly ends the test.

To optimize your script's performance, test for the most likely conditions first.

The following statements test several conditions. The term `else if` specifies alternative tests to perform if previous conditions are false:

--- Lingo syntax
if _mouse.mouseMember = member(1) then
    _movie.go("Cairo")
else if _mouse.mouseMember = member(2) then
    _movie.go("Nairobi")
else
    _player.alert("You're lost.")
end if

// JavaScript syntax
if (_mouse.mouseMember = member(1)) {
    _movie.go("Cairo");
} else if (_mouse.mouseMember = member(2)) {
    _movie.go("Nairobi");
} else {
    _player.alert("You're lost.");
}
When writing `if...then` structures in Lingo, you can place the statement or statements following `then` in the same line as `then`, or you can place them on their own line by inserting a carriage return after `then`. If you insert a carriage return, you must also include an `end if` statement at the end of the `if...then` structure.

When writing `if` structures in JavaScript syntax, you can place the statement or statements following `if` in the same line as `if`, or you can place them on their own line by inserting a carriage return after `if`.

For example, the following statements are equivalent:

```-- Lingo syntax
if _mouse.mouseMember = member(1) then _movie.go("Cairo")
if _mouse.mouseMember = member(1) then
    _movie.go("Cairo")
end if
// JavaScript syntax
if (_mouse.mouseMember = member(1)) { _movie.go("Cairo"); }
if (_mouse.mouseMember = member(1)) {
    _movie.go("Cairo");
}
```

For reference information on using the `if...then...else` and `if...else` structures, see “if” on page 209.

### Evaluating and matching expressions

The `case` (Lingo) or `switch...case` (JavaScript syntax) structures are shorthand alternatives to using `if...then...else or if...then` structures when setting up multiple branching structures. The `case and switch...case structures are often more efficient and easier to read than many `if...then...else or if...then` structures.

In Lingo, the condition to test for follows the term `case` in the first line of the `case` structure. The comparison goes through each line in order until Lingo encounters an expression that matches the test condition. When a matching expression is found, Director executes the Lingo that follows the matching expression.

In JavaScript syntax, the condition to test for follows the term `switch` in the first line of the structure. Each comparison in the test follows the term `case` for each line that contains a test. Each `case` comparison can be ended by using the optional term `break`. Including the term `break` breaks the program out of the `switch` structure and executes any statements following the structure. If `break` is omitted, the following `case` comparison is executed.

A `case or switch...case` structure can use comparisons as the test condition.

For example, the following `case and switch...case structures test which key the user pressed most recently and responds accordingly.

- If the user pressed A, the movie goes to the frame labeled Apple.
- If the user pressed B or C, the movie performs the specified transition and then goes to the frame labeled Oranges.
• If the user pressed any other letter key, the computer beeps.

-- Lingo syntax
case (_key.key) of
  "a" : _movie.go("Apple")
  "b", "c":
    _movie.puppetTransition(99)
    _movie.go("Oranges")
  otherwise: _sound.beep()
end case

// JavaScript syntax
switch (_key.key) {
  case "a":
    _movie.go("Apple");
    break;
  case "b":
    _movie.puppetTransition(99);
    _movie.go("Oranges");
    break;
  case "c":
    _movie.puppetTransition(99);
    _movie.go("Oranges");
    break;
  default: _sound.beep()
}

Note: In JavaScript syntax, only one comparison can be made per case statement.

For reference information on using case structures, see “case” on page 203.

Repeating actions

In both Lingo and JavaScript syntax, you can repeat an action a specified number of times or while a specific condition exists.

In Lingo, to repeat an action a specified number of times you use a repeat with structure. Specify the number of times to repeat as a range following repeat with.

In JavaScript syntax, to repeat an action a specified number of times you use the for structure. The for structure takes three parameters: the first parameter typically initializes a counter variable, the second parameter specifies a condition to evaluate each time through the loop, and the third parameter is typically used to update or increment the counter variable.

The repeat with and for structures are useful for performing the same operation on a series of objects. For example, the following loop makes Background Transparent the ink for sprites 2 through 10:

-- Lingo syntax
repeat with n = 2 to 10
  sprite(n).ink = 36
end repeat

// JavaScript syntax
for (var n=2; n<10; n++) {
  sprite(n).ink = 36;
}
The following example performs a similar action, but with decreasing numbers:

```
-- Lingo syntax
repeat with n = 10 down to 2
    sprite(n).ink = 36
end repeat

// JavaScript syntax
for (var n=10; n>=2; n--)
    sprite(n).ink = 36;
```

In Lingo, to repeat a set of instructions as long as a specific condition exists, use the `repeat while` structure.

In JavaScript syntax, to repeat a set of instructions as long as a specific condition exists, use the `while` structure.

For example, the following statements instruct a movie to beep continuously whenever the mouse button is being pressed:

```
-- Lingo syntax
repeat while _mouse.mouseDown
    _sound.beep()
end repeat

// JavaScript syntax
while (_mouse.mouseDown) {
    _sound.beep();
}
```

Both Lingo and JavaScript syntax scripts continue to loop through the statements inside the loop until the condition is no longer true, or until one of the statements sends the script outside the loop. In the previous example, the script exits the loop when the mouse button is released because the `mouseDown` condition is no longer true.

In Lingo, to exit a loop, use the `exit repeat` statement.

In JavaScript syntax, to exit a loop you can use the term `break`. A loop also automatically exits when a condition is no longer true.

For example, the following statements make a movie beep while the mouse button is pressed, unless the mouse pointer is over sprite 1. If the pointer is over sprite 1, the script exits the loop and stops beeping. The `rollover()` method indicates whether the pointer is over the specified sprite.

```
-- Lingo syntax
repeat while _mouse.stillDown
    _sound.beep()
    if _movie.rollover(1) then exit repeat
end repeat

// JavaScript syntax
while (_mouse.stillDown) {
    _sound.beep();
    if (_movie.rollover(1)) {
        break;
    }
}
```

For reference information on the `repeat while` and `while` structures, see “repeat while” on page 220.
Events, messages, and handlers

A key component to creating powerful, useful scripts is an understanding of the concepts and functionality of events, messages, and handlers. Understanding the order in which events and messages are sent and received will help you determine exactly when specific scripts or parts of scripts should run. It will also help you debug scripts when specific actions are not occurring when you expect them to occur.

When a movie plays, the following occurs:

1. Events occur in response to either a system or user-defined action
2. Messages that correspond to these events are sent to the scripts in a movie
3. Handlers within scripts contain the instructions that run when a specific message is received

The name of an event corresponds to the name of the message it generates, and the handler that handles the event corresponds to both the event and the message. For example, when the event named `mouseDown` occurs, Director generates and sends to scripts a message named `mouseDown`, which would in turn be handled by a handler named `mouseDown`.

Events

There are two categories of events that occur when a movie plays:

- **System events** occur without a user interacting with the movie, and are predefined and named in Director. For example, when the playhead enters a frame, when a sprite is clicked, and so on.
- **User-defined events** occur in response to actions that you define. For example, you could create an event that occurs when the background color of a sprite changes from red to blue, when a sound has played five times, and so on.

Many system events, such as `prepareFrame`, `beginSprite`, and so on, occur automatically and in a predefined order while a movie is playing. Other system events, particularly mouse events such as `mouseDown`, `mouseUp`, and so on, do not necessarily occur automatically while a movie is playing, but rather when a user triggers them.

For example, when a movie first starts, the `prepareMovie` event always occurs first, the `prepareFrame` event always occurs second, and so on. However, the `mouseDown` and `mouseUp` events may never occur in a movie unless a user triggers them by clicking the movie.

The following lists illustrate the system events that always occur during a movie, and the order in which they occur.

**When the movie first starts, events occur in the following order:**

1. `prepareMovie`
2. `prepareFrame` Immediately after the `prepareFrame` event, Director plays sounds, draws sprites, and performs any transitions or palette effects. This event occurs before the `enterFrame` event. A `prepareFrame` handler is a good location for script that you want to run before the frame draws.
3. `beginSprite` This event occurs when the playhead enters a sprite span.
4. `startMovie` This event occurs in the first frame that plays.
When the movie encounters a frame, events occur in the following order:

1. **beginSprite**  
   This event occurs only if new sprites begin in the frame.

2. **stepFrame**

3. **prepareFrame**

4. **enterFrame**  
   After **enterFrame** and before **exitFrame**, Director handles any time delays required by the tempo setting, idle events, and keyboard and mouse events.

5. **exitFrame**

6. **endSprite**  
   This event occurs only if the playhead exits a sprite in the frame.

When a movie stops, events occur in the following order:

1. **endSprite**  
   This event occurs only if sprites currently exist in the movie.

2. **stopMovie**

For reference information on the predefined system events in Director, see Chapter 10, “Events and Messages,” on page 159.

**Messages**

To run the appropriate set of script statements at the right time, Director must determine what is occurring in the movie and which statements to run in response to certain events.

Director sends messages to indicate when specific events occur in a movie, such as when sprites are clicked, keyboard keys are pressed, a movie starts, the playhead enters or exits a frame, or a script returns a certain result.

The general order in which messages are sent to objects is as follows:

1. Messages are sent first to behaviors attached to a sprite involved in the event. If a sprite has more than one behavior attached to it, behaviors respond to the message in the order in which they are attached to the sprite.

2. Messages are sent next to a script attached to the cast member assigned to the sprite.

3. Messages are then sent to behaviors attached to the current frame.

4. Messages are sent last to movie scripts.

Although you can define your own message names, most common events that occur in a movie have built-in message names.

For reference information on the built-in messages in Director, see Chapter 10, “Events and Messages,” on page 159.

**Defining custom messages**

In addition to using built-in message names, you can define your own messages and corresponding handler names. A custom message can call another script, another handler, or the statement’s own handler. When the called handler stops executing, the handler that called it resumes.

A custom message and handler name must meet the following criteria:

- It must start with a letter.
- It must include alphanumeric characters only (no special characters or punctuation).
• It must consist of one word or of several words connected by an underscore—no spaces are allowed.
• It must be different from the name of any predefined Lingo or JavaScript syntax element.

Using predefined Lingo or JavaScript keywords for message and handler names can create confusion. Although it is possible to explicitly replace or extend the functionality of a Lingo or JavaScript element by using it as a message or handler name, this should be done only in certain advanced situations.

When you have multiple handlers with similar functions, it is useful to give them names that have similar beginnings so they appear together in an alphabetical listing, such as the listing that can be displayed by the Edit > Find > Handler command.

Handlers

A handler is a set of statements within a script that runs in response to a specific event and subsequent message. Although Director contains built-in events and messages, you must create your own custom handlers for each event/message pair that you want to handle.

Deciding where to place handlers

You can place handlers in any type of script, and a script can contain multiple handlers. It’s a good idea to group related handlers in a single place, though, for easier maintenance.

The following are some useful guidelines for many common situations:

• To associate a handler with a specific sprite, or to have a handler run in response to an action on a specific sprite, put the handler in a behavior attached to the sprite.
• To set up a handler that should be available any time the movie is in a specific frame, put the handler in a behavior attached to the frame.
  For example, to have a handler respond to a mouse click while the playhead is in a frame, regardless of where the click occurs, place a mouseDown or mouseUp handler in the frame behavior rather than in a sprite behavior.
• To set up a handler that runs in response to messages about events anywhere in the movie, put the handler in a movie script.
• To set up a handler that runs in response to an event that affects a cast member, regardless of which sprites use the cast member, put the handler in a cast member script.

Determining when handlers receive a message

After sending a message to scripts, Director checks for handlers in a definite order.

1 Director first checks whether a handler exists in the object from which the message was sent. If a handler is found, the message is intercepted, and the script in the handler runs.
2 If no handler is found, Director then checks cast member, in ascending order, for any associated movie scripts that might contain a handler for the message. If a handler is found, the message is intercepted, and the script in the handler runs.
3 If no handler is found, Director then checks whether a frame script contains a handler for the message. If a handler is found, the message is intercepted, and the script in the handler runs.
4 If no handler is found, Director then checks sprites, in ascending order, for any scripts associated with the sprites that might contain a handler for the message. If a handler is found, the message is intercepted, and the script in the handler runs.
After a handler intercepts a message, the message does not automatically pass on to the remaining locations. However, in Lingo you can use the `pass()` method to override this default rule and pass the message to other objects.

If no matching handler is found after the message passes to all possible locations, Director ignores the message.

The exact order of objects to which Director sends a message depends on the message. For information on the sequence of objects to which Director sends specific messages, see the entry for each message in Chapter 10, “Events and Messages,” on page 159.

**Using parameters to pass values to a handler**

By using parameters for values, you can give the handler exactly the values that it needs to use at a specific time, regardless of where or when you call the handler in the movie. Parameters can be optional or required, depending on the situation.

**To create parameters for a handler:**

- In Lingo, put the parameters after the handler name. In JavaScript syntax, put the parameters within parentheses, and then put them after the handler name. Use commas to separate multiple parameters.

When you call a handler, you must provide specific values for the parameters that the handler uses. You can use any type of value, such as a number, a variable that has a value assigned, or a string of characters. Values in the calling statement must be in the order that they follow in the handler's parameters, and they must be surrounded by parentheses.

In the following example, the variable assignment `mySum` calls the method `addThem`, which is passed the two values 2 and 4. The `addThem` handler replaces the parameter placeholders `a` and `b` with the two values passed to it, stores the result in the local variable `c`, and then uses the keyword `return` to send the result back to the original method, which is then assigned to `mySum`.

Because 2 is first in the list of parameters, it is substituted for `a` in the handler. Likewise, because 4 is second in the list of parameters, it is substituted for `b` in the handler.

---

**Lingo syntax**

```
mySum = addThem(2, 4) -- calling statement
```

```
on addThem a, b -- handler
  c = a + b
  return c -- returns the result to the calling statement
end
```

---

**JavaScript syntax**

```
var mySum = addThem(2, 4); // calling statement
```

```
function addThem(a, b) { // handler
  c = a + b;
  return c; // returns the result to the calling statement
}
```

In Lingo, when you call a custom method from an object, a reference to the script object in memory is always passed as an implied first parameter to the handler for that method. This means that you must account for the script object reference in your handler.
For example, consider that you wrote a custom sprite method named `jump()` that takes a single integer as a parameter, and you placed the method in a behavior. When you call `jump()` from a sprite object reference, the handler must also include a parameter that represents the script object reference, and not just the single integer. In this case, the implied parameter is represented by the keyword `me`, but any term will work.

```lingo
myHeight = sprite(2).jump(5)
```

```lingo
on jump(me,a)
    return a + 15 -- this handler works correctly, and returns 20
end
```

```lingo
on jump(a)
    return a + 15 -- this handler does not work correctly, and returns 0
end
```

You can also use expressions as values. For example, the following statement substitutes `3+6` for `a` and `8>2` (or `1`, representing `TRUE`) for `b`, and would return `10`:

```lingo
mySum = addThem(3+6, 8>2)
```

In Lingo, each handler begins with the word `on` followed by the message that the handler should respond to. The last line of the handler is the word `end`. You can repeat the handler's name after `end`, but this is optional.

In JavaScript syntax, each handler begins with the word `function` followed by the message that the handler should respond to. The statements that comprise the handler are surrounded by opening and closing brackets, as are all JavaScript syntax functions.

### Returning results from handlers

Often, you want a handler to report some condition or the result of some action.

#### To return results from a handler:

- Use the keyword `return` to have a handler report a condition or the result of an action. For example, the following `findColor` handler returns the current color of sprite 1:

  ```lingo
  on findColor
      return sprite(1).foreColor
  end
  // JavaScript syntax
  function findColor() {
      return(sprite(1).foreColor);
  }
  ```

You can also use the keyword `return` by itself to exit from the current handler and return no value. For example, the following `jump` handler returns nothing if the `aVal` parameter equals 5; otherwise, it returns a value.

```lingo
on jump(aVal)
    if aVal = 5 then return
    aVal = aVal + 10
    return aVal
end
```
// JavaScript syntax
function jump(aVal) {
  if(aVal == 5) {
    return;
  } else {
    aVal = aVal + 10;
    return(aVal);
  }
}

When you define a handler that returns a result, you must use parentheses after the handler when you call it from another handler. For example, the statement `put(findColor())` calls the `findColor` handler and then displays the result in the Message window.

Linear lists and property lists

In your scripts, you may want to track and update lists of data, such as a series of names or the values assigned to a set of variables. Both Lingo and JavaScript syntax have access to linear lists and property lists. In a linear list, each element in the list is a single value. In a property list, each element in the list contains two values; the first value is a property name, and the second value is the value associated with that property.

Because both Lingo and JavaScript syntax have access to linear and property lists, it is recommended that you use linear lists and property lists if values in your code are shared between Lingo and JavaScript syntax scripts.

If values in your code are used only in JavaScript syntax scripts, it is recommended that you use JavaScript Array objects to work with lists of data. For more information on using arrays, see “JavaScript syntax arrays” on page 45.

Creating linear lists

You create a linear list in one of the following ways:

- In Lingo, use either the top level `list()` function or the list operator (`[]`), using commas to separate items in the list.
- In JavaScript syntax, use the top level `list()` function, using commas to separate items in the list.

The index into a linear list always starts with 1.

When you use the top level `list()` function, you specify the list’s elements as parameters of the function. This function is useful when you use a keyboard that does not provide square brackets.

All of the following statements create a linear list of three names and assign it to a variable.

-- Lingo syntax
workerList = ["Bruno", "Heather", "Carlos"] -- using the Lingo list operator
workerList = list("Bruno", "Heather", "Carlos") -- using list()

// JavaScript syntax
var workerList = list("Bruno", "Heather", "Carlos"); // using list()
You can also create empty linear lists. The following statements create empty linear lists.

-- Lingo syntax
workerList = [] -- using the Lingo list operator
workerList = list() -- using list() with no parameters

// JavaScript syntax
var workerList = list(); // using list() with no parameters

Creating property lists

You create a property list in one of the following ways:

• In Lingo, use either the top level propList() function or the list operator ([:]). When using
the list operator to create a property list, you can use a either a colon to designate name/value
elements and commas to separate elements in the list, or commas to both designate name/value
elements and to separate elements in the list.

• In JavaScript syntax, use the top level propList() function and insert commas to both
designate name/value elements and to separate elements in the list.

When you use the top level propList() function, you specify the property list's elements as
parameters of the function. This function is useful when you use a keyboard that does not provide
square brackets.

Properties can appear more than once in a given property list.

All of the following statements create a property list with four property names—left, top,
right, and bottom—and their corresponding values.

-- Lingo syntax
sprite1Loc = [#left:100, #top:150, #right:300, #bottom:350]
sprite1Loc = ["left", 400, "top", 550, "right", 500, "bottom", 750]
sprite1Loc = propList("left", 400, "top", 550, "right", 500, "bottom", 750)

// JavaScript syntax
var sprite1Loc = propList("left", 400, "top", 550, "right", 500, "bottom", 750);

You can also create empty property lists. The following statements create empty property lists.

-- Lingo syntax
sprite1Loc = [:] -- using the Lingo property list operator
sprite1Loc = propList() -- using propList() with no parameters

// JavaScript syntax
var sprite1Loc = propList(); // using propList() with no parameters

Setting and retrieving items in lists

You can set and retrieve individual items in a list. The syntax differs for linear and property lists.

To set a value in a linear list, do one of the following:

• Use the equals (=) operator.

• Use the setAt() method.
The following statements illustrate defining the linear list `workerList` that contains one value, Heather, and then adds Carlos as the second value in the list.

-- Lingo syntax
workerList = ["Heather"] -- define a linear list
workerList[2] = "Carlos" -- set the second value using the equal operator
workerList.setAt(2, "Carlos") -- set the second value using setAt()

// JavaScript syntax
var workerList = list("Heather"); // define a linear list
workerList[2] = "Carlos"; // set the second value using the equal operator
workerList.setAt(2, "Carlos"); // set the second value using setAt()

To retrieve a value in a linear list:

- Use the list variable followed by the number that indicates the value's position in the list. Place square brackets around the number.
- Use the `getAt()` method.

The following statements create the linear list `workerList`, and then assign the second value in the list to the variable `name2`.

-- Lingo syntax
workerList = ["Bruno", "Heather", "Carlos"] -- define a linear list
name2 = workerList[2] -- use bracketed access to retrieve "Heather"
name2 = workerList.getAt(2) -- use getAt() to retrieve "Heather"

// JavaScript syntax
var workerList = list("Bruno", "Heather", "Carlos");
var name2 = workerList[2] // use bracketed access to retrieve "Heather"
var name2 = workerList.getAt(2) // use getAt() to retrieve "Heather"

To set a value in a property list, do one of the following:

- Use the equals (=) operator.
- In Lingo only, use the `setaProp()` method.
- Use dot syntax.

The following Lingo statement uses the equals operator to make sushi the new value associated with the property Bruno.

-- Lingo syntax
foodList = [] -- define an empty property list
foodList["Bruno"] = "sushi" -- associate sushi with Bruno

The following Lingo statement uses `setaProp()` to make sushi the new value associated with the property Bruno.

-- Lingo syntax
foodList = [] -- define an empty property list
foodList.setaProp("Bruno", "sushi") -- use `setaProp()`

// JavaScript syntax
foodList = propList() -- define an empty property list
foodList.setaProp("Bruno", "sushi") -- use `setaProp()`

The following statements use dot syntax to set the value associated with Bruno from sushi to teriyaki.
To retrieve a value in a property list, do one of the following:

- Use the list variable followed by the name of the property associated with the value. Place square brackets around the property.
- Use the `getaProp()` or `getPropAt()` methods.
- Use dot syntax.

The following statements use bracketed access to retrieve the values associated with the properties `breakfast` and `lunch`.

```plaintext
-- Lingo syntax
foodList = [#breakfast:"Waffles", #lunch:"Tofu Burger"]
trace(foodList[#breakfast]) -- displays "Waffles"
trace(foodList[#lunch]) -- displays "Tofu Burger"
```

```plaintext
// JavaScript syntax
var foodList = propList("breakfast", "Waffles", "lunch", "Tofu Burger");
trace(foodList["breakfast"]); // displays Waffles
trace(foodList["lunch"]); // displays Tofu Burger
```

The following statements use `getaProp()` to retrieve the value associated with the property `breakfast`, and `getPropAt()` to retrieve the property at the second index position in the list.

```plaintext
-- Lingo syntax
foodList = [#breakfast:"Waffles", #lunch:"Tofu Burger"]
trace(foodList.getaProp(#breakfast)) -- displays "Waffles"
trace(foodList.getPropAt(2)) -- displays #lunch
```

```plaintext
// JavaScript syntax
var foodList = propList("breakfast", "Waffles", "lunch", "Tofu Burger");
trace(foodList.getaProp("breakfast")); // displays Waffles
trace(foodList.getPropAt(2)) // displays lunch
```

The following statements use dot syntax to access the values associated with properties in a property list.

```plaintext
-- Lingo syntax
foodList = [#breakfast:"Waffles", #lunch:"Tofu Burger"]
trace(foodList.breakfast) -- displays "Waffles"
```

```plaintext
// JavaScript syntax
var foodList = propList("breakfast", "Waffles", "lunch", "Tofu Burger");
trace(foodList.lunch); // displays Tofu Burger
```
Checking items in lists

You can determine the characteristics of a list and the number of items the list contains by using the following methods.

- To display the contents of a list, use the put() or trace() functions, passing the variable that contains the list as a parameter.
- To determine the number of items in a list, use the count() method (Lingo only) or the count property.
- To determine a list's type, use the ilk() method.
- To determine the maximum value in a list, use the max() method.
- To determine the minimum value in a list, use the min() function.
- To determine the position of a specific property, use the findPos, findPosNear, or getOne command.

The following statements use count() and count to display the number of items in a list.

-- Lingo syntax
workerList = ["Bruno", "Heather", "Carlos"] -- define a linear list
trace(workerList.count()) -- displays 3
trace(workerList.count) -- displays 3

// JavaScript syntax
var workerList = list(“Bruno”, “Heather”, “Carlos”); // define a linear list
trace(workerList.count); // displays 3

The following statements use ilk() to determine a list's type.

-- Lingo syntax
x = [“1”, “2”, “3”]
trace(x.ilk()) // returns #list

// JavaScript syntax
var x = list(“1”, “2”, “3”);
trace(x.ilk()) // returns #list

The following statements use max() and min() to determine the maximum and minimum values in a list.

-- Lingo syntax
workerList = ["Bruno", "Heather", "Carlos"] -- define a linear list
trace(workerList.max()) -- displays "Heather"
trace(workerList.min()) -- displays "Bruno"

// JavaScript syntax
var workerList = list(“Bruno”, “Heather”, “Carlos”); // define a linear list
trace(workerList.max()); // displays Heather
trace(workerList.min()); // displays Bruno

The following statements use findPos to get the index position of a specified property in a property list.

-- Lingo syntax
-- define a property list
foodList = [#breakfast:”Waffles”, #lunch:”Tofu Burger”]
trace(foodList.findPos(#lunch)) -- displays 2

// JavaScript syntax
// define a property list
var foodList = propList(“breakfast”, “Waffles”, “lunch”, “Tofu Burger”);
trace(foodList.findPos(“breakfast”)); // displays 1
Adding and deleting items in lists

You can add or delete items in a list by using the following methods.

- To add an item at the end of a list, use the `append()` method.
- To add an item at its proper position in a sorted list, use the `add()` or `addProp()` methods.
- To add an item at a specific place in a linear list, use the `addAt()` method.
- To add an item at a specific position in a property list, use the `addProp()` method.
- To delete an item from a list, use the `deleteAt()`, `deleteOne()`, or `deleteProp()` methods.
- To replace an item in a list, use the `setAt()` or `setaProp()` methods.

The following statements use `append()` to add an item to the end of a list.

--- Lingo syntax
```lingo
workerList = ["Bruno", "Heather", "Carlos"] -- define a linear list
workerList.append("David")
trace(workerList) -- displays ["Bruno", "Heather", "Carlos", "David"]
```

--- JavaScript syntax
```javascript
var workerList = list("Bruno", "Heather", "Carlos"); // define a linear list
workerList.append("David");
trace(workerList); // displays ["Bruno", "Heather", "Carlos", "David"]
```

The following statements use `addProp()` to add a property and an associated value to a property list.

--- Lingo syntax
```lingo
foodList = [#breakfast:"Waffles", #lunch:"Tofu Burger"]
foodList.addProp(#dinner, "Spaghetti") -- adds [#dinner: "Spaghetti"]
```

--- JavaScript syntax
```javascript
var foodList = propList("breakfast", "Waffles", "lunch", "Tofu Burger");
foodList.addProp("dinner", "Spaghetti"); // adds ["dinner": "Spaghetti"]
```

You do not have to explicitly remove lists. Lists are automatically removed when they are no longer referred to by any variable. Other types of objects must be removed explicitly, by setting variables that refer to them to `VOID` (Lingo) or `null` (JavaScript syntax).

Copying lists

Assigning a list to a variable and then assigning that variable to a second variable does not make a separate copy of the list. For example, the first statement below creates a list that contains the names of two continents, and assigns the list to the variable `landList`. The second statement assigns the same list to a new variable `continentList`. In the third statement, adding Australia to `landList` also automatically adds Australia to the list `continentList`. This happens because both variable names point to the same list object in memory. The same behavior occurs by using an array in JavaScript syntax.

--- Lingo syntax
```lingo
landList = ["Asia", "Africa"]
continentList = landList
landList.add("Australia") -- this also adds "Australia" to continentList
```
To create a copy of a list that is independent of another list:

- Use the `duplicate()` method.

For example, the following statements create a list and then make an independent copy of the list.

```lingo
oldList = ["a", "b", "c"]
newList = oldList.duplicate() -- makes an independent copy of oldList
```

```javascript
var oldList = list("a", "b", "c");
var newList = oldList.duplicate(); // makes an independent copy of oldList
```

After `newList` is created, editing either `oldList` or `newList` has no effect on the other.

### Sorting lists

Lists are sorted in alphanumeric order, with numbers being sorted before strings. Strings are sorted according to their initial letters, regardless of how many characters they contain. Sorted lists perform slightly faster than unsorted lists.

A linear list is sorted according to the values in the list. A property list is sorted according to the property names in the list or array.

After the values in a linear or property list are sorted, they will remain sorted, even as values are added to or removed from the lists.

To sort a list:

- Use the `sort()` method.

For example, the following statements sort a nonsorted alphabetical list.

```lingo
oldList = ["d", "a", "c", "b"]
oldList.sort() -- results in ["a", "b", "c", "d"]
```

```javascript
var oldList = list("d", "a", "c", "b");
oldList.sort(); // results in ["a", "b", "c", "d"]
```

### Creating multidimensional lists

You can also create multidimensional lists that enable you to work with the values of more than one list at a time.

In the following example, the first two statements create the separate linear lists `list1` and `list2`. The third statement creates a multidimensional list and assigns it to `mdList`. To access the values in a multidimensional list, the fourth and fifth statements use brackets to access the values in the list; the first bracket provides access to a specified list, and the second bracket provides access to the value at a specified index position in the list.

```lingo
list1 = list(5,10)
list2 = list(15,20)
mdList = list(list1, list2)
trace(mdList[1][2]) -- displays 10
trace(mdList[2][1]) -- displays 15
```
JavaScript syntax arrays

JavaScript syntax arrays are similar to Lingo-style linear lists in that each element in an array is a single value. One of the main differences between JavaScript syntax arrays and Lingo-style linear lists is that the index into an array always starts with 0.

You create a JavaScript syntax array by using the Array object. You can use either square brackets ([ ] ) or the Array constructor to create an array. The following two statements create an array with two values.

```javascript
// JavaScript syntax
var myArray = [10, 15]; // using square brackets
var myArray = new Array(10, 15); // using the Array constructor
```

You can also create empty arrays. The following two statements create an empty array.

```javascript
// JavaScript syntax
var myArray = []; // using square brackets
var myArray = new Array(); // using the Array constructor
```

Note: The Director Scripting Reference does not include a complete reference for JavaScript syntax Array objects. For more complete information on using Array objects, see one of the many third-party resources on the subject.

Checking items in arrays

You can determine the characteristics of an array and the number of items the array contains by using the following methods.

- To display the contents of a list, use the `put()` or `trace()` function, passing the variable that contains the list as a parameter.
- To determine the number of items in an array, use the Array object’s `length` property.
- To determine an array’s type, use the `constructor` property.

The following example illustrates determining the number of items in an array using the `length` property, and then returning the type of object using the `constructor` property.

```javascript
// JavaScript syntax
var x = ["1", "2", "3"]; // using square brackets
trace(x.length) // displays 3
trace(x.constructor == Array) // displays true
```

Adding and deleting items in arrays

You can add or delete items in an array by using the following methods:

- To add an item at the end of an array, use the Array object’s `push()` method.
- To add an item at its proper position in a sorted array, use the Array object’s `splice()` method.
- To add an item at a specific position in an array, use the Array object’s `splice()` method.
• To delete an item from an array, use the Array object's `splice()` method.
• To replace an item in an array, use the Array object's `splice()` method.

The following example illustrates using the Array object's `splice()` method to add items to, delete items from, and replace items in an array.

```javascript
// JavaScript syntax
var myArray = new Array("1", "2");
trace(myArray); // displays 1,2

myArray.push("5"); // adds the value "5" to the end of myArray
trace(myArray); // displays 1,2,5

myArray.splice(3, 0, "4"); // adds the value "4" after the value "5"
trace(myArray); // displays 1,2,5,4

myArray.sort(); // sort myArray
trace(myArray); // displays 1,2,4,5

myArray.splice(2, 0, "3");
trace(myArray); // displays 1,2,3,4,5

myArray.splice(3, 2); // delete two values at index positions 3 and 4
trace(myArray); // displays 1,2,3

myArray.splice(2, 1, "7"); // replaces one value at index position 2 with "7"
trace(myArray); // displays 1,2,7
```

### Copying arrays

Assigning an array to a variable and then assigning that variable to a second variable does not make a separate copy of the array.

For example, the first statement below creates an array that contains the names of two continents, and assigns the array to the variable `landList`. The second statement assigns the same list to a new variable `continentList`. In the third statement, adding `Australia` to `landList` also automatically adds `Australia` to the array `continentList`. This happens because both variable names point to the same Array object in memory.

```javascript
// JavaScript syntax
var landArray = new Array("Asia", "Africa");
var continentArray = landArray;
landArray.push("Australia"); // this also adds "Australia" to continentList
```

To create a copy of an array that is independent of another array:

• Use the Array object's `slice()` method.

For example, the following statements create an array and then use `slice()` to make an independent copy of the array.

```javascript
// JavaScript syntax
var oldArray = ["a", "b", "c"]; var newArray = oldArray.slice(); // makes an independent copy of oldArray
```

After `newArray` is created, editing either `oldArray` or `newArray` has no effect on the other.
Sorting arrays

Arrays are sorted in alphanumerical order, with numbers being sorted before strings. Strings are sorted according to their initial letters, regardless of how many characters they contain.

To sort an array:

- Use the Array object’s `sort()` method.

The following statements sort a non-sorted alphabetical array.

```javascript
// JavaScript syntax
var oldArray = ["d", "a", "c", "b"];
oldArray.sort(); // results in a, b, c, d
```

The following statements sort a non-sorted alphanumerical array.

```javascript
// JavaScript syntax
var oldArray = [6, "f", 3, "b"];
oldArray.sort(); // results in 3, 6, b, f
```

Sorting an array results in a new sorted array.

Creating multidimensional arrays

You can also create multidimensional arrays that enable you to work with the values of more than one array at a time.

In the following example, the first two statements create the separate arrays `array1` and `array2`. The third statement creates a multidimensional array and assigns it to `mdArray`. To access the values in a multidimensional array, the fourth and fifth statements use brackets to access the values in the array; the first bracket provides access to a specified array, and the second bracket provides access to value at a specified index position in the array.

```javascript
// JavaScript syntax
var array1 = new Array(5,10);
var array2 = [15,20];
var mdArray = new Array(array1, array2);
trace(mdArray[0][1]); // displays 10
trace(mdArray[1][0]); // displays 15
```
Scripts in Macromedia Director MX 2004 support all kinds of functionality in movies that would not be possible otherwise. As you write scripts, you may find the need for increasingly advanced scripts to support complex interactivity in your Director movies. Intermediate and advanced scripting concepts and techniques are presented here, including information about object-oriented scripting in Director.

If you are new to scripting in Director, make sure to read Chapter 2, “Director Scripting Essentials,” on page 9 in addition to the topics here.

Choosing between Lingo and JavaScript syntax

Both Lingo and JavaScript syntax provide access to the same objects, events, and scripting APIs. Therefore, it does not necessarily matter which language you choose to write your scripts. Your choice might be as simple as deciding which language you have the most knowledge of and are most comfortable with.

To understand how scripting languages typically work with a given object and event model in Director, consider the following:

- In general, a given scripting language, such as Lingo or JavaScripts syntax, is wrapped around a given object and event model in order to provide access to those objects and events.
- JavaScript is an implementation of the ECMA Script standard that is wrapped around a web browser’s object and event model to provide access to the browser’s objects and events.
- ActionScript is an implementation of the ECMA Script standard that is wrapped around the Macromedia Flash object and event model to provide access to Flash objects and events.
- The Director implementation of JavaScript syntax is an implementation of ECMAScript that is wrapped around the Director object and event model to provide access to Director objects and events.
- Lingo is a custom syntax that is wrapped around the Director object and event model to provide access to Director objects and events.

Lingo and JavaScript syntax are the two languages you can use to access the same Director object and event model. Scripts written in one language have the same capabilities as scripts written in the other language.
Therefore, after you know how to access the scripting APIs in one language, you essentially know how to access them in the other language. For example, JavaScript syntax code can access Lingo data types such as symbols, linear lists, property lists, and so on, create and invoke Lingo parent scripts and behaviors, create and invoke Xtra extensions, and use Lingo string chunk expressions. Also, both JavaScript syntax and Lingo scripts can be used within a single movie; however, a single script cast member can contain only one syntax or the other.

There are two main differences between Lingo and JavaScript syntax:

- Each language contains some terminology and syntax conventions that are unique to each language. For example, the syntax for an event handler is different in Lingo than it is in JavaScript syntax:
  ```
  -- Lingo syntax
  on mouseDown
    ...
  end
  // JavaScript syntax
  function mouseDown() {
    ...
  }
  
  For more information on the terminology and syntax conventions used for each language, see “Scripting terminology” on page 10 and “Scripting syntax” on page 12.

- Some of the scripting APIs are accessed slightly differently in each language. For example, you would use different constructs to access the second word in the first paragraph of a text cast member:
  ```
  -- Lingo syntax
  member("News Items").paragraph[1].word[2]
  // JavaScript syntax
  member("News Items").getPropRef("paragraph", 1).getProp("word", 2);
  ```

Scripting in dot syntax format

Whether you write scripts in Lingo or JavaScript syntax, you write them by using the dot syntax format. You use dot syntax to access the properties or methods related to an object. A dot syntax statement begins with a reference to an object, followed by a period (dot), and then the name of the property, method, or text chunk that you want to specify. Each dot in a statement essentially represents a move from a higher, more general level in the object hierarchy to a lower, more specific level in the object hierarchy.

For example, the following statement first creates a reference to the cast library named "News Stories", and then uses dot syntax to access the number of cast members in that cast library.

  ```
  -- Lingo syntax
  castLib("News Stories").member.count
  // JavaScript syntax
  castLib("News Stories").member.count;
  ```
To identify chunks of text, include terms after the dot to refer to more specific items within text. For example, the first statement below refers to the first paragraph of the text cast member named "News Items". The second statement below refers to the second word in the first paragraph.

-- Lingo syntax
member("News Items").paragraph[1]
member("News Items").paragraph[1].word[2]

// JavaScript syntax
member("News Items").getPropRef("paragraph", 1);
member("News Items").getPropRef("paragraph", 1).getProp("word", 2);

For certain objects that handle cascading property access to either data or a specific cast member type, as illustrated in the previous two statements, access to the properties is not supported by using normal JavaScript syntax. Therefore, you must use the `getPropRef()` and `getProp()` methods to access cascading properties in JavaScript syntax.

There are a few things to note about this JavaScript syntax exception:

- This technique must be applied to 3D objects, text cast members, field cast members, and XML Parser Xtra extensions accessed by using JavaScript syntax.
- You must use the `getPropRef()` method to store a reference to one of the previously mentioned objects or its properties by using JavaScript syntax.
- You must use the `getProp()` method to retrieve a property value of one of the previously mentioned objects or its properties by using JavaScript syntax.
- 3D objects and properties must be accessed by using their fully qualified names in JavaScript syntax. For example, in Lingo, the property `shader` can be used as a shortcut for the property `shaderList[1]`. However, in JavaScript syntax, the property `shaderList[1]` must be used at all times.

**Introducing the Director objects**

In basic terms, objects are logical groupings of named data that also can contain methods that act on that data. In this release of Director, the scripting APIs have been grouped into objects and are accessed through these objects. Each object provides access to a specific set of named data and type of functionality. For example, the Sprite object provides access to the data and functionality of a sprite, the Movie object provides access to the data and functionality of a movie, and so on.

The objects used in Director fall into the following four categories. Depending on the type of functionality you want to add and the part of a movie you are adding functionality to, you will use the objects from one or more of these categories:

- **Core objects**
- **Media types**
- **Scripting objects**
- **3D objects**
Core objects

This category of objects provides access to the core functionality and features available in Director, such as the Director player engine, movie windows, sprites, sounds, and so on. They represent the base layer through which all APIs and other object categories are accessed.

There are also a group of top-level methods and properties that enable you to access all of the core objects directly, instead of having to traverse the object hierarchy to access a specific core object.

For a reference of the available core objects and their APIs, see Chapter 5, “Director Core Objects,” on page 101.

Media types

This category of objects provides access to the functionality of the various media types, such as RealMedia, DVD, Animated GIF, and so on, which are added to movies as cast members.

Literally, media types are not actually objects, but rather cast members that are of a specific type of media. When a media type is added to a movie as a cast member, it not only inherits the functionality of the core Member object, it also extends the Member object by providing additional functionality that is available only to the specified media type. For example, a RealMedia cast member has access to the Member object’s methods and properties, but it also has additional methods and properties that are specific to RealMedia. All other media types also exhibit this behavior.

For a reference of the available media types and their APIs, see Chapter 6, “Media Types,” on page 119.

Scripting objects

This category of objects, also known as Xtra extensions, provides access to the functionality of the software components, such as XML Parser, Fileio, SpeechXtra, and so on, that are installed with Director and extend core Director functionality. The preexisting Xtra extensions provide capabilities such as importing filters and connecting to the Internet. If you know the C programming language, you can create your own custom Xtra extensions.

For a reference of the available scripting objects and their APIs, see Chapter 7, “Scripting Objects,” on page 137.

3D objects

This category of objects provides access to the functionality of the cast members and text that are used to create 3D movies.

For more information about 3D movies, see the Using Director topics in the Director Help Panel.

For a reference of the available 3D objects and their APIs, see Chapter 8, “3D Objects,” on page 141.
Object model diagrams

The following diagrams illustrate the basic high-level relationships between the object groups and their hierarchies within Director. For information on object creation, properties and methods, and other APIs, see the relevant API reference topics.
Top level functions and properties

There are a number of top level functions and properties that provide direct access to the core objects and functionality in Director. You will likely make extensive use of many of these functions and properties as you create references to core objects, new images, lists, and so on. For example, the top level _movie property refers directly to the core Movie object, and the top level list() function creates a linear list.

The following tables list the top level functions and properties.

### Top level functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>

Introduction to object-oriented programming in Director

By using either Lingo or JavaScript syntax, you can apply object-oriented programming principles to your scripts. Applying object-oriented principles typically makes programming easier by letting you write less code and letting you use simpler logic to accomplish tasks, in addition to increasing the reusability and modularity of your code.

Depending on the scripting language you are using, you apply these principles using two different paradigms:

- In Lingo, you use parent scripts, ancestor scripts, and child objects to simulate object-oriented programming.
- In JavaScript syntax, you use standard JavaScript-style object-oriented programming techniques to create classes and subclasses.
Each paradigm enables you to apply the advantages of object-oriented programming to your scripts, so it does not really matter which scripting language you are using. You merely apply the principles in different ways.

Because each scripting language uses a different paradigm to apply object-oriented principles, the techniques described for one language won't work in the other language. Therefore, you only need to read the content that applies to the scripting language you are using:

- For more information on simulating object-oriented programming in Lingo, see “Object-oriented programming with Lingo” on this page.
- For more information on object-oriented programming in JavaScript syntax, see “Object-oriented programming with JavaScript syntax” on page 65.

Object-oriented programming with Lingo

In Lingo, parent scripts provide the advantages of object-oriented programming. You can use parent scripts to generate script objects that behave and respond similarly yet can still operate independently of each other.

You can create multiple copies (or instances) of a parent script by using Lingo. Each instance of a parent script is called a child object. You can create child objects on demand as the movie plays. Director does not limit the number of child objects that can be created from the same parent script. You can create as many child objects as the computer's memory can support.

Director can create multiple child objects from the same parent script, just as Director can create multiple instances of a behavior for different sprites. You can think of a parent script as a template and of child objects as implementations of the parent template.

The discussion about Lingo parent scripts and child objects describes the basics of how to write parent scripts and create and use child objects, and also provides script examples. It does not teach fundamental object-oriented programming concepts; however, to use parent scripts and child objects successfully, you must understand object-oriented programming principles. For an introduction to the basics of object-oriented programming, see one of the many third-party resources on that subject.

Similarity to other object-oriented languages

If you are familiar with an object-oriented programming language such as Java or C++, you may already understand the concepts that underlie parent scripting but know them by different names. Terms that Director uses to describe parent scripts and child objects correspond to the following common object-oriented programming terms:

**Parent scripts** in Director correspond to classes in object-oriented programming.

**Child objects** in Director correspond to instances in object-oriented programming.

**Property variables** in Director correspond to instance variables or member variables in object-oriented programming.

**Handlers** in Director correspond to methods in object-oriented programming.

**Ancestor scripts** in Director correspond to the Super class or base class in object-oriented programming.
Parent script and child object basics

In Lingo, a parent script is a set of handlers and properties that define a child object; it is not a child object itself. A child object is a self-contained, independent instance of a parent script. Children of the same parent have identical handlers and properties, so child objects in the same group can have similar responses to events and messages.

Typically, parent scripts are used to build child objects that make it easier to organize movie logic. These child objects are especially useful when a movie requires the same logic to be run several times concurrently with different parameters. You can also add a child object to a Sprite object’s scriptInstanceList or the Movie object’s actorList as a way to control animation.

Because all the child objects of the same parent script have identical handlers, those child objects respond to events in similar ways. However, because each child object maintains independent values for the properties defined in the parent script, each child object can behave differently than its sibling objects—even though they are instances of the same parent script.

For example, you can create a parent script that defines child objects that are editable text fields, each with its own property settings, text, and color, regardless of the other text fields’ settings. By changing the values of properties in specific child objects, you can change any of these characteristics as the movie plays without affecting the other child objects based on the same parent script.

Similarly, a child object can have a property set to either TRUE or FALSE regardless of that property’s setting in sibling child objects.

A parent script refers to the name of a script cast member that contains the property variables and handlers. A child object created from a parent script is essentially a new instance of the script cast member.

Differences between child objects and behaviors

While child objects and behaviors are similar in that they both can have multiple instances, they have some important differences as well. The main difference between child objects and behaviors is that behaviors are associated with locations in the Score because they are attached to sprites. Behavior objects are automatically created from initializers stored in the Score as the playhead moves from frame to frame and encounters sprites with attached behaviors. In contrast, child objects from parent scripts must be created explicitly by a handler.

Behaviors and child objects differ in how they become associated with sprites. Director automatically associates a behavior with the sprite that the behavior is attached to, but you must explicitly associate a child object with a sprite. Child objects do not require sprite references and exist only in memory.

Ancestor basics

Parent scripts can declare ancestors, which are additional scripts whose handlers and properties a child object can call on and use.

Ancestor scripting lets you create a set of handlers and properties that you can use and reuse for multiple parent scripts.
A parent script makes another parent script its ancestor by assigning the script to its ancestor property. For example, the following statement makes the script What_Everyone_Does an ancestor to the parent script in which the statement occurs:

```-- Lingo syntax
ancestor = new(script "What_Everyone_Does")
```

When handlers and properties are not defined in a child object, Director searches for the handler or property in the child’s ancestors, starting with the child’s parent script. If a handler is called or a property is tested and the parent script contains no definition for it, Director searches for a definition in the ancestor script. If a definition exists in the ancestor script, that definition is used.

A child object can have only one ancestor at a time, but that ancestor script can have its own ancestor, which can also have an ancestor, and so on. This lets you create a series of parent scripts whose handlers are available to a child object.

**Writing a parent script**

A parent script contains the code needed to create child objects and define their possible actions and properties. First, you must decide how you want the child objects to behave. Then, you can write a parent script that does the following:

- Optionally declares any appropriate property variables; these variables represent properties for which each child object can contain a value independent of other child objects.
- Sets up the initial values of the child objects’ properties and variables in the `on new` handler.
- Contains additional handlers that control the child objects’ actions.

**Declaring property variables**

Each child object created from the same parent script initially contains the same values for its property variables. A property variable’s value belongs only to the child object it’s associated with. Each property variable and its value persists as long as the child object exists. The initial value for the property variable is typically set in the `on new` handler; if it’s not set, the initial value is `VOID`.

To declare a property variable:

- Use the `property` keyword at the beginning of the parent script.

To set and test property variables from outside the child object:

- Set and test property variables in the same way you would any other property in your scripts, by using the syntax `objectRef.propertyName`.

For example, the following statement sets the `speed` property of an object `car1`:

```car1.speed = 55```

**Creating the new handler**

Each parent script typically uses an `on new` handler. This handler creates the new child object when another script issues a `new(script parentScriptName)` command, which tells the specified parent script to create a child object from itself. The `on new` handler in the parent script can also set the child object’s initial property values, if you want.

The `on new` handler always starts with the phrase `on new`, followed by the `me` variable and any parameters being passed to the new child object.
The following on new handler creates a new child object from the parent script and initializes the child's spriteNum property with the value passed to it in the aSpriteNum parameter. The return statement returns the child object to the handler that originally called the on new handler.

```
-- Lingo syntax
property spriteNum

on new me, aSpriteNum
    spriteNum = aSpriteNum
    return me
end
```

For more information on calling the on new handlers, see “Creating a child object” on page 59.

Adding other handlers
You determine a child object’s behavior by including in the parent script the handlers that produce the desired behavior. For example, you could add a handler to make a sprite change color.

The following parent script defines a value for the property spriteNum, and contains a second handler that changes the foreColor property of the sprite.

```
-- Lingo syntax
property spriteNum

on new me, aSpriteNum
    spriteNum = aSpriteNum
    return me
end

on changeColor me
    spriteNum.foreColor = random(255)
end
```

Referring to the current object
Typically, one parent script creates many child objects, and each child object contains more than one handler. The special parameter variable me tell the handlers in a child object that they are to operate on the properties of that object and not on the properties of any other child object. This way, when a handler within a child object refers to properties, the handler uses its own child object’s values for those properties.

The term me must always be the first parameter variable stated in every handler definition in a parent script. It is always important to define me as the first parameter for parent scripts and to pass the same parameter if you need to call other handlers in the same parent script, since these will be the handlers in each of the script’s child objects.

When referring to properties defined in ancestor scripts, you must use the me parameter as the source of the reference. This is because the property, while defined in the ancestor script, is nevertheless a property of the child object. For example, the following statement uses me to refer to an object and access properties defined in an ancestor of the object:

```
-- Lingo syntax
x = me.y -- access ancestor property y
```

Because the variable me is present in each handler of a child object, it indicates that all the handlers control that same child object.
Creating a child object

Child objects exist entirely in memory; they are not saved with a movie. Only parent and ancestor scripts exist on disk.

To create a new child object, you use the `new()` method and assign the child object a variable name or position in a list so you can identify and work with it later.

To create a child object and assign it to a variable, use the following syntax.

```-- Lingo syntax
variableName = new(script "scriptName", parameter1, parameter2, ...)
```

The `scriptName` parameter is the name of the parent script, and `parameter1, parameter2, ...` are any parameters you are passing to the child object's `on new` handler. The `new()` method creates a child object whose ancestor is `scriptName`. It then calls the `on new` handler in the child object with the specified parameters.

You can issue a `new()` statement from anywhere in a movie. You can customize the child object's initial settings by changing the values of the parameters passed with the `new()` statement.

Each child object requires only enough memory to record the current values of its properties and variables and a reference to the parent script. Because of this, in most cases, you can create and maintain as many child objects as you require.

You can produce additional child objects from the same parent script by issuing additional `new()` statements.

You can create child objects without immediately initializing their property variables by using the `rawNew()` method. The `rawNew()` method does this by creating the child object without calling the parent script's `on new` handler. In situations where large numbers of child objects are needed, `rawNew()` allows you to create the objects ahead of time and defer the assignment of property values until each object is needed.

The following statement creates a child object from the parent script Car without initializing its property variables and assigns it to the variable car1:

```-- Lingo syntax
car1 = script("Car").rawNew()
```

To initialize the properties of one of these child objects, call its `on new` handler:

```
car1.new
```

Checking child object properties

You can check the values of specific property variables in individual child objects by using a simple `objectName.propertyName` syntax. For example, the following statement assigns the variable `x` the value of the `carSpeed` property of the child object in the variable `car1`:

```-- Lingo syntax
x = car1.carSpeed
```

Querying object properties from outside the objects themselves can be useful for getting information about groups of objects, such as the average speed of all the car objects in a racing game. You might also use the properties of one object to help determine the behavior of other objects that are dependent on it.
In addition to checking the properties that you assign, you can check whether a child object contains a specific handler or find out which parent script an object came from. This is useful when you have objects that come from parent scripts that are similar but that have subtle differences.

For example, you may want to create a scenario in which one of several parent scripts might be used to create a child object. You can then determine which parent script a particular child object came from by using the script() function, which returns the name of an object’s parent script.

The following statements check whether the object car1 was created from the parent script named Car:

```-- Lingo syntax
if car1.script = script("Car") then
    _sound.beep()
end if
```

You can also get a list of the handlers in a child object by using the handlers() method, or check whether a particular handler exists in a child object by using the handler() method.

The following statement places a list of the handlers in the child object car1 into the variable myHandlerList:

```-- Lingo syntax
myHandlerList = car1.handlers()
```

The resulting list would look something like this:

```
[start, #accelerate, stop]
```

The following statements use the handler() method to check whether the handler on accelerate exists in the child object car1:

```-- Lingo syntax
if car1.handler(#accelerate) then
    put("The child object car1 contains the handler named on accelerate.")
end if
```

Removing a child object

You can remove a child object from a movie by setting all variables that contain a reference to the child object to another value. If the child object has been assigned to a list, such as actorList, you must also remove the child object from the list.

**To remove a child object and the variables that refer to it:**

- Set each variable to VOID.

Director deletes the child object when there are no more references to it. In the following example, ball1 contains the only reference to a specific child object, and it is set to VOID to delete the object from memory.

```-- Lingo syntax
ball1 = VOID
```

**To remove an object from actorList:**

- Use the delete() method to delete the item from the list.
**Using scriptInstanceList**

You can use the `scriptInstanceList` property to dynamically add new behaviors to a sprite. Normally, `scriptInstanceList` is the list of behavior instances created from the behavior initializers defined in the Score. If you add child objects created from parent scripts to this list, the child objects receive the messages sent to other behaviors.

For example, the following statement adds a child object to the `scriptInstanceList` property of sprite 10:

```lingo
-- Lingo syntax
add(sprite(10).scriptInstanceList, new(script "rotation", 10))
```

The following is a possible parent script that the previous statement refers to:

```lingo
-- Lingo syntax parent script "rotation"
property spriteNum
on new me, aSpriteNum
    spriteNum = aSpriteNum
    return me
end

on prepareFrame me
    sprite(spriteNum).rotation = sprite(spriteNum).rotation + 1
end
```

When a child object is added to `scriptInstanceList`, you must initialize the child object’s `spriteNum` property. Typically, you do this from a parameter passed in to the `on new` handler.

**Note:** The `beginSprite` message is not sent to dynamically added child objects.

For reference information on `scriptInstanceList`, see “scriptInstanceList” on page 964.

**Using actorList**

You can set up a special list of child objects (or any other objects) that receives its own message each time the playhead enters a frame or the `updateStage()` method updates the Stage.

The special list is `actorList`, which contains only objects that have been explicitly added to the list.

The message is the `stepFrame` message that is sent only when the playhead enters a frame or the `updateStage()` command is used.

Objects in `actorList` receive a `stepFrame` message instead of an `enterFrame` message at each frame. If the objects have an `on stepFrame` handler available, the script in the handler runs each time the playhead enters a new frame or the `updateStage()` method updates the Stage.

Some possible uses of `actorList` and `stepFrame` are to animate child objects that are used as sprites or to update a counter that tracks the number of times the playhead enters a frame.

An `on enterFrame` handler could achieve the same results, but the `actorList` property and `stepFrame` handler are optimized for performance in Director. Objects in `actorList` respond more efficiently to `stepFrame` messages than to `enterFrame` messages or custom messages sent after an `updateStage()` method.
To add an object to the actorList:

- Use the actorList property as follows, where childObject is a reference to the child object to add:

  -- Lingo syntax
  _movie.actorList.add(childObject)

  The object's stepFrame handler in its parent or ancestor script then runs automatically each
time the playhead advances. The object is passed as the first parameter, me, to the on
stepFrame handler.

  Director does not clear the contents of actorList when branching to another movie, which can
cause unpredictable behavior in the new movie. If you do not want child objects in the current
movie to be carried over into the new movie, insert a statement that clears actorList in the on
prepareMovie handler of the new movie.

To clear child objects from actorList:

- Set actorList to [], which is an empty list.

  For reference information on actorList, see “actorList” on page 621.

Creating timeout objects

A timeout object is a script object that acts like a timer and sends a message when the timer
expires. This is useful for scenarios that require specific things to happen at regular time intervals
or after a particular amount of time has elapsed.

Timeout objects can send messages that call handlers inside child objects or in movie scripts. You
create a timeout object by using the new() keyword. You must specify a name for the object, a
handler to be called, and the frequency with which you want the handler to be called. After a
timeout object is created, Director keeps a list of currently active timeout objects, called
timeOutList.

To create timeout objects:

- Use either syntax below:

  --Lingo syntax
  variableName = timeOut(timeOutObjName).new(intMilliseconds, #handlerName \1, targetObject)

  variableName = new timeOut(timeOutObjName, intMilliseconds, #handlerName \1, targetObject)

  This statement uses the following elements:

  - variableName is the variable you are placing the timeout object into.
  - timeOut indicates which type of Lingo object you are creating.
  - timeOutObjName is the name you give to the timeout object. This name appears in the
timeOutList. It is the #name property of the object.
  - new creates a new object.
  - intMilliseconds indicates the frequency with which the timeout object should call the
    handler you specify. This is the #period property of the object. For example, a value of 2000
calls the specified handler every 2 seconds.
• **handlerName** is the name of the handler you want the object to call. This is the 
  `#timeoutHandler` property of the object. You represent it as a symbol by preceding the name 
  with the `#` sign. For example, a handler called `on accelerate` would be specified as 
  `#accelerate`.

• **targetObject** indicates which child object’s handler should be called. This is the `#target` 
  property of the object. It allows specificity when many child objects contain the same handlers. 
  If you omit this parameter, Director looks for the specified handler in the movie script.

The following statement creates a timeout object named `timer1` that calls an `on accelerate` 
handler in the child object `car1` every 2 seconds:

```lingo
-- Lingo syntax
myTimer = timeOut("timer1").new(2000, #accelerate, car1)
```

To determine when the next timeout message will be sent from a particular timeout object, check 
its `#time` property. The value returned is the point in time, in milliseconds, when the next 
timeout message will be sent. For example, the following statement determines the time when 
the next timeout message will be sent from the timeout object `timer1` and displays it in the 
Message window:

```lingo
-- Lingo syntax
put(timeout("timer1").time)
```

Using `timeOutList`

When you begin creating timeout objects, you can use `timeOutList` to check the number of 
timeout objects that are active at a particular moment.

The following statement sets the variable `x` to the number of objects in `timeOutList` by using the 
count property.

```lingo
-- Lingo syntax
x = _movie.timeoutList.count
```

You can also refer to an individual timeout object by its number in the list.

The following statement deletes the second timeout object in `timeOutList` by using the 
`forget()` method.

```lingo
-- Lingo syntax
timeout(2).forget()
```

Relaying system events with timeout objects

When you create timeout objects that target specific child objects, you enable those child objects 
to receive system events. Timeout objects relay these events to their target child objects. The 
system events that can be received by child objects include `prepareMovie, startMovie, 
stopMovie, prepareFrame, and exitFrame`. By including handlers for these events in child 
objects, you can make the child objects respond to them for whatever purposes you see fit. System 
events received by child objects are also received by movie scripts, frame scripts, and other scripts 
designed to respond to them.
The following parent script contains a handler for the system event `exitFrame` and a custom handler `slowDown`.

```
-- Lingo syntax
property velocity

on new me
    velocity = random(55)
end

on exitFrame
    velocity = velocity + 5
end

on slowDown mph
    velocity = velocity - mph
end
```

**Associating custom properties with timeout objects**

If you want to associate custom properties with a timeout object, you may want to create a timeout object that uses as a target anything other than a reference to a script instance object. When you use this technique, the target data becomes data that is associated with the timeout object, and can be used in your timeout handler.

The following example illustrates using this technique.

```
-- Lingo syntax
-- initialize a timeout object and pass it a data property list (tData)
-- instead of a reference to a script instance object
tData = [#beta: 0]
tTO = timeout("betaData").new(50,#targetHandler,tData)

-- within a movie script, create the targetHandler handler
on targetHandler (aData)
    -- increment and display the beta property
    tData.beta = tData.beta + 1
    put(tData.beta)
end targetHandler
```

In the previous example, the beta property keeps incrementing. This means that you can initialize several timeout objects that all call the same movie script handler, and each timeout object can have its own data list associated with it.

In general, keep the following in mind:

- When using a reference to a script instance as a target, the target handler in that particular script instance is called. This technique does now allow the use of custom properties.
- When using a reference to anything other than a script instance (such as a property list) as a target, the target handler in a movie script is called. This technique allows the use of custom properties.
Object-oriented programming with JavaScript syntax

Object-oriented programming in JavaScript syntax is somewhat different than it is in other object-oriented languages such as Java and C++—while some object-oriented languages are class-based, JavaScript syntax is prototype-based.

The following two bullet points compare and contrast, at a high level, class-based languages with prototype-based languages such as JavaScript syntax.

• In class-based languages, you create class definitions that define the initial properties and methods that characterize all instances created from those classes. A class definition contains special methods, called constructor methods, that are used to create the instances of that class. When an instance is created by using the `new` operator in association with a particular constructor method, that instance inherits all the properties of its parent class. That instance can also perform other processing specific to that instance depending on the constructor that was called.

  In a class definition, you perform inheritance by creating a subclass that inherits all the properties of its parent class, in addition to defining new properties and optionally modifying inherited ones. The parent class from which a subclass is created is also known as a super-class.

• In prototype-based languages, such as JavaScript syntax, there is no distinction between classes, instances, subclasses, and so on—they are all known as objects. Instead of using class definitions, in JavaScript syntax you use “prototype objects” as the template from which new objects are created. Similar to class-based languages, in JavaScript syntax, you create a new object by using the `new` operator in association with a constructor function.

  Instead of using super-classes and subclasses, in JavaScript syntax, you associate prototype objects with constructor functions to perform inheritance. This process is very similar to using super-classes and subclasses, only with different terminology.

  Also, as opposed to class-based languages, in JavaScript syntax you can add and remove properties from an object or set of objects at runtime. For example, if you add a property to a prototype object at runtime, any instance objects for which it is a prototype also get that property.

Object-oriented terminology

Because all types in JavaScript syntax are known as objects, class-based terms such as `super-class`, `subclass`, `class`, `instance`, and so on do not have literal technical meanings in JavaScript syntax. However, all of these terms essentially map to objects in JavaScript syntax, and are convenient to use generically when referring to the different types of JavaScript syntax objects. Therefore, these class-based terms are used interchangeably with `object` throughout the discussion about object-oriented programming in JavaScript syntax to mean the following:

• superclass Any class from which subclasses (objects) are created; a parent class.

• subclass Any class that has been created from a superclass (object); a child class.

• class A generic term for a superclass or subclass; a parent or child class.

• instance or object instance A single object that has been created from a superclass.
Custom classes

One of the major advantages of object-oriented programming is the ability to create your own custom classes that enable you to add custom functionality to your scripts. The predefined classes provided by JavaScript syntax, such as Object, String, Math, and so on are useful in some cases, but they may not provide the functionality you require to accomplish your task. For example, suppose you want some objects in your movie to represent types of transportation, such as cars, boats, planes, and so on, and that you want each category to exhibit unique characteristics and functionality. Neither the predefined JavaScript syntax classes nor the predefined Director objects may directly provide the functionality that you need. Therefore, you may want to create a new class for each type of transportation so you can define unique characteristics for each type.

Keep in mind that when you create custom JavaScript syntax classes, you still have access to all the features and functionality of the predefined Director objects. This means that although the predefined Director objects may not directly provide the functionality that you need, you can still use them in your custom classes to access their values and predefined functionality.

Constructor functions

In JavaScript syntax, a constructor function represents the class that contains the template from which new object instances are created. Constructor functions create and initialize (set the default state of) properties in the new objects.

Constructor functions are essentially identical in format to regular JavaScript syntax method functions. The difference between a constructor function and a method function is that a constructor function uses the special `this` keyword to represent a reference to the new object that is being initialized. A method function typically only performs some action on a given set of an object's data.

The following example illustrates one way to create a Rectangle constructor function that could be used to initialize the height and width of new Rectangle objects.

```javascript
function Rectangle(w, h) {
  this.width = w;
  this.height = h;
}
```

You can also create a constructor function by using "function literal" syntax. Function literal syntax provides the same functionality as the syntax used previously, and is merely an alternative way to write the constructor. The following example illustrates using function literal syntax to create a Rectangle constructor function similar to the one illustrated previously.

```javascript
Rectangle = function(w, h) {
  this.width = w;
  this.height = h;
}
```

**Note:** When defining constructor functions that apply to a movie, be sure to place them in a movie script so they are available globally.

It is considered good scripting practice to give constructor functions names that map to their functionality, and to use initial capitalization in their names, such as `Rectangle` or `Circle`.

Constructor functions are typically used only to initialize new objects, but can also return the object if desired. If you do return the initialized object, the returned object becomes the value of the `new` expression.
Object instances

The most common way to create a new object instance is to use the `new` operator followed by the name of a constructor function. The following examples create new object instances.

```javascript
var objRandom = new Object(); // assigns a reference to an Object object
var objString = new String(); // assigns a reference to a String object
```

A constructor function can optionally define parameters that a new object instance passes to it to initialize the state of the object instance. If a constructor function does define parameters used during initialization of new object instances, the property values are initialized as follows:

- If you pass values to the constructor function during initialization, the properties that received values are set to those values.
- If you do not pass values to the constructor function during initialization, the properties that did not receive values are set to `undefined`.

When you create new object instances, the keyword `this` is used in the body of the associated constructor function to refer to the new object instance. Therefore, a new object instance is initialized with all of the properties defined by using the `this.propertyName` syntax.

In the following example, a `Circle` constructor function uses the keyword `this` to specify the names of three properties that will be associated with new object instances. The statement following the constructor initializes a new object instance by passing values to the constructor. These values are used as the initial values of the properties specified by the keyword `this`.

```javascript
// Circle constructor function
function Circle(x, y, r) {
    this.xCoord = x;
    this.yCoord = y;
    this.radius = r;
}

// xCoord = 10, yCoord = 15, radius = 5
var objCircle = new Circle(10, 15, 5);
```

Now that `objCircle` has been initialized, you can access its properties. Using the `objCircle` instance created previously, you could set some variables equal to the values of its properties.

```javascript
var theXCoord = objCircle.xCoord; // assigns the value 10 to theXCoord
var theYCoord = objCircle.yCoord; // assigns the value 15 to theYCoord
var theRadius = objCircle.radius; // assigns the value 5 to theRadius
```

**Note:** For more information on using dot syntax to access properties and methods of an object, see "Scripting in dot syntax format" on page 50.

It is considered good scripting practice to give new objects names that map to their functionality, and to name them by using lowercase letters, such as `objRectangle` or `objCircle`.

You can also create an object instance by using "object literal" syntax, which eliminates the need for the `new` operator and a constructor function. You typically only use this technique when you need only one instance of an object that has not been defined in a constructor function. The following example creates an object instance with `x = 1, y = 2, and radius = 2`.

```javascript
var objSmallCircle = { x:1, y:2, radius:2 };
**Object inheritance**

In addition to being able to create your own custom classes, another major advantage of object-oriented programming is the ability of subclasses to inherit the properties and methods of the superclasses from which they were created. Inheritance enables you to easily create objects that already have built-in properties and functionality.

In JavaScript syntax, there is one superclass that acts as the base class from which all other subclasses are created—the Object superclass. The Object superclass contains a few basic properties and methods. The subclasses that are created by using Object as a template always inherit these basic properties and methods, and likely define their own properties and methods. Subclasses of these classes inherit from Object, from their superclasses, and so on. All additional objects that you create would continue this chain of inheritance.

For example, Object contains the `constructor` property and the `toString()` method. If you create a new class named `SubObj1`, it is a subclass of Object, and therefore automatically inherits the `constructor` property and the `toString()` method of Object. If you then create another class named `SubObj2` using `SubObj1` as a superclass, `SubObj2` would also inherit the `constructor` property and the `toString()` method of Object, in addition to any custom properties and methods you defined in `SubObj1`.

Two of the important properties that your custom constructor functions inherit from the Object superclass are `prototype` and `constructor`. The `prototype` property represents the prototype object of a class, which enables you to add variables (properties) and methods to object instances, and is the means by which inheritance is typically implemented in JavaScript syntax. The `constructor` property represents the constructor function itself. The use of these properties is explained in the following sections.

**Prototype objects**

As previously stated, when you create a subclass, it automatically inherits the properties and methods of the superclass on which it is based. In JavaScript syntax, inheritance is typically implemented by using prototype objects. A subclass actually inherits its properties and methods from the prototype object of its superclass, and not from the superclass itself. This important point offers a distinct advantage: all properties and methods do not literally have to be copied from a class to an object instance of that class, which can dramatically decrease the amount of memory required by new object instances.

Every class in JavaScript syntax, including the predefined Object class, contains only one prototype object. Every object instance created from a class has access to the properties and methods in the prototype object of that class. Therefore, the prototype object of a class is typically the only object that actually stores the properties and methods for that class; an object instance only contains the properties required to initialize that instance.

In your code, it appears that each object instance actually contains those properties and methods because you can access them directly from each object instance, but the instance is actually using the prototype object to access them. The prototype object of a class is created automatically when you create the class. You access the prototype object by using the `prototype` property of the class.

Because a prototype object of a class stores properties that are shared by all object instances, they are ideally suited to define properties and methods whose values will be shared across all object instances. By sharing properties and methods across object instances, you can easily create instances that exhibit a defined default behavior, and can also customize any instances that deviate from the default behavior.
Prototype objects typically are not suited to define properties and methods whose values may vary across object instances. In cases where values may vary across object instances, you typically define those properties and methods within the class itself.

To specify the scope of a custom property or method, you define it as one of the following four types:

- **Instance variables**
- **Instance methods**
- **Class variables**
- **Class methods**

### Instance variables

Instance variables are any variables (properties) that are defined in a constructor function and that are copied into each object instance of that constructor. All object instances have their own copies of instance variables. This means that if there are five object instances of a `Circle` class, there are five copies of each instance variable defined in the class. Because each object instance has its own copy of an instance variable, each object instance can assign a unique value to an instance variable without modifying the values of other copies of the instance variable. You access instance variables directly from their containing object instances.

The following example defines four instance variables—`make`, `model`, `color`, and `speed`—in a constructor function. These four instance variables are available directly from all object instances of the `Car` constructor.

```javascript
function Car(make, model, color) { // define a Car class
  this.make = make;
  this.model = model;
  this.color = color;
  this.speed = 0;
}
```

The following object instance `objCar` contains all four instance variables. Although a value for the instance variable `speed` is not passed to the `Car` constructor, `objCar` still has a `speed` property whose initial value is 0 because the `speed` variable is defined in the `Car` constructor.

```javascript
// objCar.make="Subaru", objCar.model="Forester",
// objCar.color="silver", objCar.speed = 0
var objCar = new Car("Subaru", "Forester", "silver");
```

### Instance methods

Instance methods are any methods that are accessible through an object instance. Object instances do not have their own copies of instance methods. Instead, instance methods are first defined as functions, and then properties of the constructor function's prototype object are set to the function values. Instance methods use the keyword `this` in the body of the defining constructor function to refer to the object instance they are operating on. Although a given object instance does not have a copy of an instance method, you still access instance methods directly from their associated object instances.
The following example defines a function named `Car_increaseSpeed()`. The function name is then assigned to the `increaseSpeed` property of the `Car` class’s prototype object.

```javascript
// increase the speed of a Car
function Car_increaseSpeed(x) {
  this.speed += x;
  return this.speed;
}
Car.prototype.increaseSpeed = Car_increaseSpeed;

An object instance of `Car` could then access the `increaseSpeed()` method and assign its value to a variable by using the following syntax.

```javascript
var objCar = new Car("Subaru", "Forester", "silver");
var newSpeed = objCar.increaseSpeed(30);
```

You can also create an instance method by using function literal syntax. Using function literal syntax eliminates the need to define a function, and the need to assign a property name to the function name.

The following example uses function literal syntax to define an `increaseSpeed()` method that contains the same functionality as the `increaseSpeed()` function defined previously.

```javascript
// increase the speed of a Car
Car.prototype.increaseSpeed = function(x) {
  this.speed += x;
  return this.speed;
}
```

### Class variables

Also known as `static` variables, these are any variables (properties) that are associated with a class, and not an object instance. There is always only one copy of a class variable, regardless of the number of object instances that are created from that class. Class variables do not use the prototype object to implement inheritance. You access a class variable directly through the class, and not through an object instance; you must define a class in a constructor function before you can define class variables.

The following example defines two class variables—`MAX_SPEED` and `MIN_SPEED`.

```javascript
function Car() { // define a Car class
  ...
}

Car.MAX_SPEED = 165;
Car.MIN_SPEED = 45;

You would access the `MAX_SPEED` and `MIN_SPEED` class variables directly from the `Car` class.

```javascript
var carMaxSpeed = Car.MAX_SPEED; // carMaxSpeed = 165
var carMinSpeed = Car.MIN_SPEED; // carMinSpeed = 45
```

### Class methods

Also known as `static` methods, these are any methods that are associated with a class, and not an object instance. There is always only one copy of a class method, regardless of the number of object instances that are created from that class. Class methods do not use the prototype object to implement inheritance. You access a class method directly through the class, and not through an object instance; you must define a class in a constructor function before you can define class methods.
The following example defines a function named `setInitialSpeed()` that can change the default speed of new car instances. The function name is assigned to the `setInitialSpeed` property of the `Car` class.

```javascript
function Car(make, model, color) { // define a Car class
    this.make = make;
    this.model = model;
    this.color = color;
    this.speed = Car.defaultSpeed;
}
Car.defaultSpeed = 10; // initial speed for new Car instances
// increase the speed of a Car
function Car_setInitialSpeed(x) {
    Car.defaultSpeed = x;
}
Car.setInitialSpeed = Car_setInitialSpeed;
```

You access the `setInitialSpeed()` class method directly from the `Car` class.

```javascript
var newSpeed = Car.setInitialSpeed(30);
```

You can also create a class method by using function literal syntax. The following example uses function literal syntax to define a `setInitialSpeed()` method that contains the same functionality as the `setInitialSpeed()` function defined previously.

```javascript
// increase the speed of a Car
Car.setInitialSpeed = function(x) {
    Car.defaultSpeed = x;
}
```

**Recommended steps for defining a class**

The following list describes the recommended steps to follow when defining a class:

1. Define a constructor function that is used as the template from which all object instances are initialized. You may additionally define any instance variables in the constructor function by using the keyword `this` to refer to an object instance.

2. Define any instance methods, and possibly additional instance variables, that are stored in the prototype object of a class. These instance methods and variables are available to all object instances, and are accessible through the prototype object of the class.

3. Define any class methods, class variables, and constants that are stored in the class itself. These class methods and variables are accessible only through the class itself.

In your code, when you access a property of an object instance, JavaScript syntax searches the object instance itself for that property. If the instance does not contain the property, JavaScript syntax then searches the prototype object of the super-class from which the instance was created. Because an object instance is searched before the prototype object of the class from which it was created, object instance properties essentially hide properties from the prototype object of their super-classes. This means that both an object instance and its super-class could realistically define a property with the same name but different values.
Deleting variables

You can delete a class variable or an instance variable by using the delete operator. The following example illustrates this process.

```javascript
function Car() { // define a Car constructor function
  ...
  Car.color = "blue"; // define a color property for the Car class
  Car.prototype.engine = "V8"; // define an engine property for the prototype
}

var objCar = new Car();
trace(Car.color); // displays "blue"
trace(objCar.engine); // displays "V8"

delete Car.color;
delete Car.prototype.engine;
trace(Car.color); // displays undefined
trace(objCar.engine); // displays undefined
```

Accessing the constructor property of a prototype object

When you define a class by creating a constructor function, JavaScript syntax creates a prototype object for that class. When the prototype object is created, it initially includes a constructor property that refers to the constructor function itself. You can use the constructor property of a prototype object to determine the type of any given object.

In the following example, the constructor property contains a reference to the constructor function used to create the object instance. The value of the constructor property is actually a reference to the constructor itself and not a string that contains the constructor's name.

```javascript
function Car() { // define a Car class
  // initialization code here
}

var myCar = new Car(); // myCar.constructor == function Car() {}
```

Creating properties dynamically

Another advantage of using prototype objects to implement inheritance is that properties and methods that are added to a prototype object are automatically available to object instances. This is true even if an object instance was created before the properties or methods were added.

In the following example, the color property is added to the prototype object of a Car class after an object instance of Car has already been created.

```javascript
function Car(make, model) { // define a Car class
  this.make = make;
  this.model = model;
}

var myCar = new Car("Subaru", "Forester"); // create an object instance

trace(myCar.color); // returns undefined

// add the color property to the Car class after myCar was initialized
Car.prototype.color = "blue";

trace(myCar.color); // returns "blue"
```
You can also add properties to object instances after the instances have been created. When you add a property to a specific object instance, that property is available only to that specific object instance. Using the `myCar` object instance created previously, the following statements add the `color` property to `myCar` after it has already been created.

```javascript
trace(myCar.color); // returns undefined
myCar.color = "blue"; // add the color property to the myCar instance
trace(myCar.color); // returns "blue"

var secondCar = new Car("Honda", "Accord"); // create a second object instance
trace(secondCar.color); // returns undefined
```

### Writing scripts in the Script window

When you write scripts for a movie, the quantity and variety of scripts can be very large. Deciding which methods or properties to use, how to structure scripts effectively, and where scripts should be placed requires careful planning and testing, especially as the complexity of your movie grows.

Before you begin writing scripts, formulate your goal and understand what you want to achieve. This is as important—and typically as time-consuming—as developing storyboards for your work.

When you have an overall plan for the movie, you are ready to start writing and testing scripts. Expect this to take time. Getting scripts to work the way you want often takes more than one cycle of writing, testing, and debugging.

The best approach is to start simple and test your work frequently. When you get one part of a script working, start writing the next part. This approach helps you identify bugs efficiently and ensures that your scripts are solid as they become more complex.

When you write your scripts, you write them in the Script window in the Director user interface. The Script window provides a number of features that help you create and modify your scripts.

**To open the Script window, do one of the following:**

- Select Window > Script.
- Double-click a script cast member in the Cast window.

For information on alternative ways to create and open scripts, see “Performing common tasks” on page 79.
Setting Script window preferences

You can change the font of text in the Script window and define different colors for various code components. To change the default font of text in the Script window and the color of various code elements, you use Script window preferences. Director automatically colors different types of code elements unless you turn off Auto Coloring.

To set Script window preferences:

1. Select Edit > Preferences > Script.
2. To choose the default font, click the Font button and select settings from the Font dialog box.
3. To choose the default color of text in the Script window, select a color from the Color menu.
4. To choose the background color for the Script window, select a color from the Background color menu.
5. To make new Script windows automatically color certain code elements, select Auto Coloring. This option is on by default. With Auto Coloring off, all text appears in the default color.
6. To make new Script windows automatically format your scripts with proper indenting, select Auto Format. This option is on by default.
   
   **Note:** The auto coloring and auto formatting features do not apply to JavaScript syntax code. Therefore, if you are authoring scripts using JavaScript syntax, the Auto Coloring and Auto Format buttons in the Script window are disabled, and terms such as `function`, `var`, and `this` will appear in the default text color.

7. To make new Script windows display line numbers for your scripts, select Line Numbering. This option is on by default.

8. If Auto Coloring is on, select colors for the following code elements from the corresponding color menus:
   - Keywords
   - Comments
   - Literals
   - Custom (terms you define in your own code)

9. To change the line number column background color, click the Line Numbers color menu and choose a new color.

10. To change the location of the Call Stack, Variable, and Watcher panes in the Debugger window, select left, top, right, or bottom from the Debugger Panes menu.
Inserting common scripting terms

The Script window provides pop-up menus of common scripting terms that you can use to insert statements in a script. The same menus also appear in the Message window.

In both the Script window and the Message window, you can select which scripting syntax you want to use for a particular script.

To select the scripting syntax:

• From the Script Syntax pop-up menu, select either Lingo or JavaScript.

After you select a scripting syntax, you enter code in the syntax you have chosen. If you try to compile a script in a syntax other than the one you chose, a script error occurs.

When entering scripts in the Script window, you can comment out or uncomment either single or multiple lines of code by using the Comment or Uncomment buttons. Depending on which scripting syntax you have chosen, the Comment and Uncomment buttons display the correct comment markers for that syntax; Lingo uses double-hyphens (--) and JavaScript syntax uses double-slashes (//).

To comment code:

• Highlight the line or lines of code you want to comment out, and click Comment.

Note: When using the Comment button to comment out multiple lines of JavaScript syntax code, Director inserts double slashes before each line. You can also comment out multiple lines of code by inserting /* before the first line of commented code and inserting */ after the last line of commented code, but you must do this manually.

To uncomment code:

• Highlight the line or lines of code that you want to remove comments from, and click Uncomment.

Both the Script window and the Message window contain the following menus:

• The Alphabetical Lingo menu lists every element in alphabetical order, except 3D Lingo.
• The Categorized Lingo menu lists categories of elements according to the features they are often used for. It does not include 3D Lingo.
• The Alphabetical 3D Lingo menu lists all 3D Lingo elements in alphabetical order.
The Categorized 3D Lingo menu lists categories of all 3D Lingo elements according to the features they are used for.

The Scripting Xtras pop-up menu includes the methods and properties of all scripting Xtra extensions found, regardless of whether they are Macromedia or third-party Xtra extensions.

**Note:** The scripting Xtra extensions listed in the Scripting Xtras pop-up menu are only those that support the `interface()` method and whose names actually appear in the pop-up menu. Although some cast member media types such as 3D and DVD also support the `interface()` method, they do not appear in the Scripting Xtras pop-up menu because they are not implemented in Director as scripting Xtra extensions.

When you select an element from the pop-up menus, Director inserts the element at the insertion point in the Script window.

When an element requires additional parameters, placeholder names are included that indicate the additional required information. When more than one argument or parameter is required, the first one is highlighted for you, so all you must do is type to replace it. You must select and change the other parameters yourself.

Some cast member types and scripting Xtra extensions provide scripting terms that do not appear in the pop-up menus. These member types and Xtra extensions often have their own documentation, and you can find some information from within Director.

**To display a list of available Xtra extensions:**

- Issue either `put(_player.xtraList)` or `trace(_player.xtraList)` in the Message window.

**To display a list of available scripting Xtra extensions:**

- Issue either `put(_player.scriptingXtraList)` or `trace(_player.scriptingXtraList)` in the Message window.

**To display a list of methods and properties for an Xtra extension:**

- From the Scripting Xtras pop-up menu, point to an Xtra extension, and on the submenu, click `put interface`. The methods and properties for that Xtra extension appear in the Message window.

### Entering and editing text

Entering and editing text in a Script window is similar to entering and editing text in any other field.

The following are common editing tasks that you perform in the Script window:

- To select a word, double-click the word.
- To select an entire script, select Select All from the Edit menu.
- To start a new line, enter a carriage return.
- In Lingo, to wrap a long line of code with a continuation symbol, press Alt+Enter (Windows) or Option+Return (Macintosh) where you want to insert a soft line break. The continuation symbol (`\`) that appears indicates that the statement continues on the next line.

In JavaScript syntax, to wrap a long line of code, insert a regular line break by pressing Enter (Windows) or Return (Macintosh). The Lingo continuation symbol causes a script error in JavaScript syntax scripts.
Finding handlers and text in scripts

The Find command in the Edit menu is useful for finding handlers and for finding and editing text and handlers.

To find handlers in scripts:

1. Select Edit > Find > Handler.
   
   The Find Handler dialog box appears.
   
   The left-most column in the Find Handler dialog box displays the name of each handler in the movie. The middle column displays the number of the cast member associated with the handler's script, along with the name of that cast member. The rightmost column lists the cast library that contains the cast member.
   
2. Select the handler that you want to find.
   
3. Click Find.
   
   The handler appears in the Script window.
   
   The title bar at the top of the Script window indicates the script's type.
To find text in scripts:
1  Make the Script window active.
2  Select Edit > Find > Text.
   The Find Text dialog box appears.

3  Enter text that you want to find in the Find field, and then click Find.
   By default, find is not case-sensitive: ThisHandler, thisHandler, and THISHANDLER are all the
   same for search purposes. Click the Case Sensitive check box to make the find case-sensitive.

To specify which cast members to search:
•  Select the appropriate option under Search: Scripts.

To start the search over from the beginning after the search reaches the end:
•  Select the Wrap-Around option.

To search only for whole words and not fragments of other words that match the word:
•  Select the Whole Words Only option.

To find the next occurrence of the text specified in the Find field:
•  Select Edit > Find Again.

To find occurrences of selected text:
1  Select the text.
2  Select Edit > Find > Selection.
Performing common tasks

The following are ways to perform common tasks for creating, attaching, and opening scripts.

To create a frame behavior (script attached to a frame):

- Double-click the behavior channel in the frame to which you want to attach the behavior.

When you create a new behavior, the behavior receives the cast library number of the first available location in the current Cast window.

When you create a new frame behavior, the Script window opens and already contains the Lingo on exitFrame handler. The first line contains on exitFrame, followed by a line with a blinking insertion point, and then a line with the word end. This makes it easy for you to quickly attach a common Lingo behavior to the frame. To make this handler work with JavaScript syntax, replace on exitFrame with function exitFrame() {, and replace end with }.

One of the most common frame behaviors is one that keeps the playhead looping in a single frame. This can be useful when you want your movie to keep playing in a single frame while waiting for the user to click a button or for a digital video or sound to finish playing.

To keep the playhead in a single frame:

- In a frame behavior, type the following statement on the line after the on exitFrame (Lingo) or function exitFrame() (JavaScript syntax) statement:

  -- Lingo syntax
  _movie.go(_movie.frame)

  // JavaScript syntax
  _movie.go(_movie.frame);

The Movie object's frame property refers to the frame currently occupied by the playhead. This statement essentially tells the playhead to "go back to the frame you are currently in."
To create a sprite behavior (script attached to a sprite):

- In the Score or on the Stage, select the sprite that you’re attaching the behavior to. Then select Window > Behavior Inspector and select New Behavior from the Behavior pop-up menu.

When you create a new sprite behavior, the Script window opens and already contains the Lingo `on mouseUp` handler. The first line contains the line `on mouseUp`, followed by a line with a blinking insertion point, and then a line with the word `end`. This makes it easy for you to quickly attach a common behavior to the sprite. To make this handler work with JavaScript syntax, replace `on mouseUp` with `function mouseUp() {`, and replace `end` with `}`.

To open a behavior for editing:

1. Double-click the behavior in the Cast window.
   - The Behavior inspector opens.
2. Click the Script Window icon in the Behavior inspector.
   - The Script window displays the behavior.

Alternatively, you can open the Script window and cycle through the scripts until you reach the behavior.

To remove a behavior from a Score location:

- Select the location and then delete the script from the list displayed in the Property inspector (Behavior tab).

To attach existing behaviors to sprites or frames, do one of the following:

- Drag a behavior from a cast to a sprite or frame in the Score or (for sprites) to a sprite on the Stage.
- In the score, select the sprites or frames that you’re attaching the behavior to. Then select Window > Behavior Inspector and select the existing behavior from the Behavior pop-up menu.

To create a movie script (script attached to a movie), do one of the following:

- If the current script in the Script window is a movie script, click the New Script button in the Script window. (Clicking the New Script button always creates a script of the same type as the current script.)
- If the current script in the Script window is not a movie script, click the New Script button and then change the new script’s type with the Script Type pop-up menu in the Script tab of the Property inspector.
- If no sprites or scripts are selected in the cast, Score, or Stage, then open a new Script window; this creates a new movie script by default.

To open a movie script or parent script for editing:

- Double-click the script in the Cast window.

To change a script’s type:

1. Select the script in the Cast window or open it in the Script window.
2. Click the Script tab of the Property inspector and select a script type from the Script Type pop-up menu.
To cycle through the scripts in the Script window:

- Use the Previous Cast Member and Next Cast Member arrows at the top of the Script window
to advance or back up to a script.

To duplicate a script:

- Select the script in the Cast window and select Duplicate from the Edit menu.

To create a script that is attached automatically to every sprite made from a specific cast member,
attach the script to the cast member itself.

To create a script attached to a cast member or open an existing one, do one of the following:

- Right-click (Windows) or Control-click (Macintosh) on a cast member in the Cast window
and select Cast Member Script from the context menu.
- Select a cast member in the Cast window and then click the Cast Member Script button in the
Cast window.

Using linked scripts

In addition to scripts stored as internal cast members, you can choose to keep scripts in external
text files and link them to your Director movie. These linked scripts are similar to linked image or
digital video files that you can import into Director movies.

Advantages of using linked scripts include the following:

- One person can work on the Director file while another works on the script.
- You can easily exchange scripts with others.
- You can control the scripts separately from the Director file in a source code control
application such as Microsoft Visual SourceSafe or Perforce by Perforce Software. Applications
such as this prevent multiple programmers working on the same Director project from
overwriting each other’s work.

Linked scripts are used by Director only during authoring. At runtime, Director projectors and
Macromedia Shockwave Player use a special internal copy of the script data stored in the movie.
This way, your linked scripts need not be distributed with your movies and cannot be copied by
end users.

To import a script as a linked text file:

1. Select File > Import.
2. Select Script as the type of file to import.
3. Select the script file(s) you want to import.
   - You can import files with the file extensions .txt, .ls, or .js. The .ls extension is the Director
     linked script extension.
   - To create a list of files you want to import, you can use the Add and Add All buttons. This is
     especially useful if you want to import scripts from multiple locations.
4. Select Link to External File from the Media pop-up menu.
5. Click Import.
You can edit linked scripts normally in the Director Script window. Changes you make are written to the external files each time you save your Director movie. (If you imported the linked script from a UNIX server, UNIX line endings are preserved.) If you import a script whose text file is locked, you won’t be able to edit the script in Director.

You cannot apply custom text colors to linked scripts in the Script window. Script auto coloring, however, is enabled for linked scripts.

To turn an internal script cast member into an external, linked script cast member:
1 Select the internal cast member and click the Script tab of the Property inspector.
2 Click Link Script As.
3 Enter a name for the script file in the Save As dialog box.
4 Click Save.

To reload a linked script after it is edited:
• Use the Member object’s unload() method.

If a linked script is edited outside of Director, you can reload it by using the unload() method in the Message window. The following statement causes the script member myScript to be unloaded and then reloaded:

```
-- Lingo syntax
member("myScript").unload()

// JavaScript syntax
member("myScript").unload();
```
CHAPTER 4
Debugging Scripts in Director

Scripts do not always do what you want the first time. The script often has an error in its syntax: possibly a word is misspelled or a small part of the script is missing. Other times, the script might work but does not produce the expected result. Mistakes or bugs almost always occur when writing your scripts, so you should allow enough time for debugging when you develop multimedia titles.

As your skill with scripting increases, you’ll probably encounter different types of problems as you master one area but start learning others. However, the basic troubleshooting techniques described here are useful for novice and advanced users alike.

The best way to correct a bug in your scripts varies from situation to situation. There are not one or two standard procedures that resolve the problem. You must use a variety of tools and techniques, such as the following:

• An overview and understanding of how scripts in the movie interact with each other
• Familiarity and practice with common debugging methods

The following tools help you identify problems in scripts:

• The Message window, when tracing is on, displays a record of the frames that play and the handlers that run in the movie.
• The Debugger window displays the values of global variables, properties of the script that is currently running, the sequence of handlers that ran to get to the current point, and the value of variables and expressions that you select.
• The Script window lets you enter comments, insert stopping points in the script, and select variables whose value is displayed in the Object inspector.
• The Object inspector lets you view and set the values of objects and properties you select.
Good scripting habits

Good scripting habits can help you avoid many scripting problems in the first place.

- Try to write your scripts in small sets of statements and test each one as you write it. This isolates potential problems where they are easier to identify.
- Insert comments that explain what the script statements are intended to do and what the values in the script are for. This makes it easier to understand the script if you return to it later or if someone else works on it. For example, the comment in the following statements make the purpose of the if...then structure and repeat loop clear:
  ```-- Lingo syntax
  -- Loop until the "s" key is pressed
  repeat while not(_key.keyPressed("s"))
    _sound.beep()
  end repeat
  
  // JavaScript syntax
  // Loop until the "s" key is pressed
  while(!_key.keyPressed("s")) {
    _sound.beep();
  }
```
- Make sure that the script's syntax is correct. Use the Script window's pop-up menus to insert pre-formatted versions of scripting elements. Rely on the API topics of this reference to check that statements are set up correctly.
- Use variable names that indicate the variables' purpose. For example, a variable that contains a number should be called something like `newNumber` instead of `ABC`.

Basic debugging

Debugging involves strategy and analysis, not a standard step-by-step procedure. This section describes the basic debugging approaches that programmers successfully use to debug any code, not just Lingo or JavaScript syntax.

Before you modify a movie significantly, always make a backup copy. It may help to name the copies incrementally, for example, `fileName_01.dir`, `fileName_02.dir`, `fileName_03.dir`, and so on to keep track of the various stages of a movie.

Identifying the problem

It might seem obvious, but the first thing to do when debugging is to identify the problem. Is a button doing the wrong thing? Is the movie going to the wrong frame? Is a field not editable when it should be?

You may also want to determine what you expect a particular script to do, and then compare your expectation with what the script actually does. This process helps you clearly define your goal and see what parts of the goal are not being met.

If you copied a script or a portion of a script from another movie or from a written example, check whether the script was designed for some specific conditions. Perhaps it requires that a sprite channel is already scripted. Maybe cast member names must follow a specific style convention.
Locating the problem

Do the following to start locating a problem:

- Think backwards through the chain to identify where the unexpected started to happen.
- Use the Message window to trace which frames the movie goes through and the handlers that your scripts run.
- Determine what the scripts should be doing and consider what in these statements relates to the problem. For example, if a text cast member is not editable when you expect it to be, where in the movie does (or does not) your script set the cast member’s `editable` property?
- If a sprite does not change as intended on the Stage, is the `updateStage()` method needed somewhere?
- Does the problem occur only on certain computers and not others? Does it happen only when the display is set to millions of colors? Maybe something in the computer is interfering with the application.

You can focus on specific lines of script by inserting a breakpoint—a point where the script pauses its execution and invokes the Debugger window—in a line. This gives you a chance to analyze conditions at that point before the script proceeds. For information on how to insert breakpoints in a script, see “Debugging in the Debugger window” on page 94.

Solving simple problems

When finding a bug, it’s a good idea to check for simple problems first.

The first debugging test occurs when you compile your script. You can compile your script by doing one of the following:

- In the Script window, click Recompile All Modified Scripts.
- From the Control menu, click Recompile All Scripts.
- Press Shift+F8.
- Close the Script window.

It is typically more convenient to compile scripts by using one of the first three options. The fourth option requires that you close the Script window each time you want to compile a script.

When you compile your script, Macromedia Director MX 2004 gives you an error message if the script contains incorrect syntax. The message usually includes the line in which the problem was first detected. A question mark appears at the spot in the line where Director first found the problem.

For example, the first line in the previous error message tells you that the script error in question is a syntax error, and also tells you what the syntax error is. The second line in the error message displays the actual line of code that contains the syntax error.
Looking for syntax errors

Syntax errors are probably the most common bug encountered while scripting. When a script fails, it is a good idea to first make sure that:

- Terms are spelled correctly, spaces are in the correct places, and necessary punctuation is used. Director cannot interpret incorrect syntax.
- Quotation marks surround the names of cast members, labels, and strings within a statement.
- All necessary parameters are present. The specific parameters depend on the individual element. See the API topic entries in this reference to determine any additional parameters that an element requires.

Looking for other simple bugs

If your script compiles without an error message, it might contain a bug. If your script is not doing what you want, check the following:

- Values for parameters are correct. For example, using an incorrect value for the number of beeps that you want the `beep()` method to generate gives you the wrong number of beeps.
- Values that change—such as variables and the content of text cast members—have the values you want. You can display their values in the Object inspector by selecting the name of the object and clicking Inspect Object in the Script window, or in the Message window by using the `put()` or `trace()` functions.
- The scripting elements do what you think they do. You can check their behavior by referring to the API topic entries in this reference.
- If the script is written in JavaScript syntax, the script may contain a capitalization error. JavaScript syntax is case-sensitive, which means that all methods, functions, properties, and variables must be referred to by using the correct capitalization.

If you attempt to call a method or function by using incorrect capitalization, you will receive a script error.

If you attempt to access a variable or property by using incorrect capitalization, you may not receive a script error, but your script may not behave as expected. For example, the following `mouseUp` handler contains a statement that attempts to access the `itemLabel` property by using incorrect capitalization. This script does not produce a script error, but instead dynamically creates a new variable with the incorrect capitalization. The value of the newly created variable is `undefined`.

```javascript
// JavaScript syntax
function beginSprite() {
    this.itemLabel = "Blue prints";
}

function mouseUp() {
    trace(this.itemLabel) // creates the itemLabel property
}
```
Debugging in the Script window

The Script window contains several features that can help you debug scripts.

To open the Script window:
• Select Window > Script.

To make the current line of code a comment:
• Click Comment.

To remove commenting from the current line of code:
• Click Uncomment.

To turn breakpoints in the current line of code on and off:
• Click Toggle Breakpoint.

To turn off all breakpoints.
• Click Ignore Breakpoints.

To add the selected expression or variable to the Object inspector:
• Click Inspect Object.

Debugging in the Message window

The Message window provides a way for you to test scripting commands and to monitor what is happening in your scripts while a movie plays.

To open the Message window:
• Select Window > Message.
Managing the Message window

The Message window has an Input pane and an Output pane. The Input pane is editable. The Output pane is read-only. The only way to display text in the Output pane is by calling the \texttt{put()} or \texttt{trace()} functions.

You can adjust the sizes of the Input and Output panes by dragging the horizontal divider that separates them.

To resize the Output pane:

• Drag the horizontal divider to a new position.

To hide the Output pane completely:

• Click the Collapse/Expand button in the center of the horizontal divider.

  When the Output pane is hidden, output from scripts that execute is displayed in the Input pane.

To display the Output pane if it is hidden:

• Click the Collapse/Expand button again.

To clear the contents of the Message window:

• Click the Clear button.

  If the Output pane is visible, its contents are deleted.

  If the Output pane is not visible, the contents of the Input pane are deleted.

To delete a portion of the contents of the Output pane:

1 Select the text to be deleted.

2 Press the Backspace or Delete key.

To copy text in the Input or Output pane:

1 Select the text.

2 Select Edit > Copy.

Testing scripts in the Message window

You can test Lingo and JavaScript syntax statements to see how they work by entering them in the Message window and observing the results. When you enter a command in the Message window, Director executes the command immediately, regardless of whether a movie is playing.

Before entering the statements you want to test, you must first select which scripting syntax, Lingo or JavaScript syntax, you are going to test.

To select the scripting syntax:

1 From the Script Syntax pop-up menu, select either Lingo or JavaScript.

To test a one-line statement:

1 Type the statement directly in the Message window.

2 Press Enter (Windows) or Return (Macintosh). Director executes the statement.

If the statement is valid, the Message window displays the result of the statement in the Output pane at the bottom of the window. If the script is invalid, an alert appears.
For example, if you type the following statement into the Message window:

```-- Lingo syntax
put(50+50)
```

```// JavaScript syntax
trace(50+50);
```

and press Enter (Windows) or Return (Macintosh), the result appears in the Output pane:

```-- Lingo syntax
-- 100
```

```// JavaScript syntax
// 100
```

If you type the following statement into the Message window:

```-- Lingo syntax
_movie.stage.bgColor = 255
```

```// JavaScript syntax
_movie.stage.bgColor = 255;
```

and press Enter (Windows) or Return (Macintosh), the Stage becomes black.

You can test multiple lines of code all at once by copying and pasting statements into the Message window or by pressing Shift+Return after each line of code.

**To execute multiple lines of code by copying and pasting:**

1. Copy the lines of code to the clipboard.
2. Enter a blank line in the Message window.
3. Paste the code into the input pane of the Message window.
4. Place the insertion point at the end of the last line of code.
5. Press Control+Enter (Windows) or Control+Return (Macintosh). Director finds the first blank line above the insertion point and executes each line of code after the blank line in succession.

**To enter multiple lines of code manually:**

1. Enter a blank line in the Message window.
2. Enter the first line of code.
3. Press Shift+Return at the end of the line.
4. Repeat steps 2 and 3 until you have entered the last line of code.
5. Press Control+Enter (Windows) or Control+Return (Macintosh). Director finds the first blank line above the insertion point and executes each line of code after the blank line in succession.

You can test a handler without running the movie by writing the handler in a Movie Script or Behavior Script window, and then by calling it from the Message window.

**To test a handler:**

1. Copy and paste or manually enter a multiline handler into the Message window as described in the previous two procedures.
2. Place the insertion point at the end of the last line of code.
3. Press Enter (Windows) or Return (Macintosh). The handler executes.
   Any output from `put()` or `trace()` statements in the handler appears in the Message window.
Like the Script window, the Message window contains pop-up menus of scripting commands. When you select a command from one of the pop-up menus, the command appears in the Message window with the first argument that you must provide selected. Several menus are provided to give you easy access to the whole catalog of scripting terms.

The pop-up menus include the following:

- **Alphabetical Lingo** includes all commands except 3D Lingo, presented in an alphabetical list.
- **Categorized Lingo** includes all commands except 3D Lingo, presented in a categorized list.
- **Alphabetical 3D Lingo** includes all 3D Lingo, presented in an alphabetical list.
- **Categorized 3D Lingo** includes all 3D Lingo, presented in a categorized list.
- **Scripting Xtra extensions** includes the methods and properties of all scripting Xtra extensions found, regardless of whether they are Macromedia or third-party Xtra extensions.

**Note:** The scripting Xtra extensions listed in the Scripting Xtras pop-up menu are only those that support the `interface()` method and whose names actually appear in the pop-up menu. Although some cast member media types such as 3D and DVD also support the `interface()` method, they do not appear in the Scripting Xtras pop-up menu because they are not implemented in Director as scripting Xtra extensions.

### Monitoring scripts in the Message window

You can set the Output pane of the Message window to display a record of the statements that a movie executes as it plays. This is useful for tracking the flow of your code and seeing the result of specific statements. You can do this in one of two ways.

**To display statements in the Output pane, do one of the following:**

- On the Message window, click **Trace**.
- Set the Movie object’s `traceScript` property to **TRUE**.

Entries after a double equal sign (==) indicate what has occurred in the movie—such as which frame the movie has just entered, which script is running, or the result of a method or setting a value.

For example, the following line indicates several things:

```plaintext
== Frame: 39  Script: 1  Handler: mouseUp
```

- The movie entered frame 39.
- The movie ran script 1, the first script attached to the frame.
- The movie ran the `mouseUp` handler in script 1 after the movie entered the frame.
Entries after an arrow made up of a double hyphen and right angle bracket (--> ) indicate lines of your code that have run. For example, the following Lingo lines:

--> _sound.fadeOut(1, 5*60)
--> if leftSide < 10 then
--> if leftSide < 200 then
--> _movie.go("Game Start")

indicate that these Lingo statements have run. Suppose you were trying to determine why the playhead did not go to the frame labeled "Game Start." If the line --> _movie.go("Game Start") never appeared in the Message window, maybe the condition in the previous statement was not what you expected.

The Message window Output pane can fill with large amounts of text when the Trace button is on. To delete the contents of the Output pane, click the Clear button. If the Output pane is not visible, the contents of the Input pane are deleted.

You can keep track of the value of variables and other objects by selecting the name of the object in the Message window and clicking the Inspect Object button. The object is added to the Object inspector, where its value is displayed and updated as the movie plays. For more information on the Object inspector, see "Debugging in the Object inspector" on page 91.

When you are in debugging mode, you can follow how a variable changes by selecting it in the Message window and then clicking the Watch Expression button. Director then adds the variable to the Watcher pane in the Debugger window, where its value is displayed and updated as you work in the Debugger window. For more information on the Watcher pane, see "Debugging in the Debugger window" on page 94.

Debugging in the Object inspector

With the Object inspector, you can view and set properties of many kinds of objects that are not displayed in the Property inspector. These include scripting objects such as global variables, lists, child objects from parent scripts, all 3D cast member properties, sprite properties, script expressions, and so on. In addition, the Object inspector displays changes to object properties that occur while a movie plays, such as changes due to scripts or changes to sprite Score properties. These kinds of runtime changes are not displayed in the Property inspector during movie playback.

To open the Object inspector:
• Select Window > Object Inspector.
Understanding object structure

The Object inspector can be very useful for understanding the structure of complex objects. For example, 3D cast members have many layers of properties. Because the Object inspector shows you a visual representation of the nested structure of those properties, it makes it much easier to become familiar with them and their relationships to each other. Understanding the property structure of objects in Director is important when writing scripts.

The ability to watch the values of properties change while a movie plays is helpful for understanding what is happening in the movie. It is especially helpful when testing and debugging scripts because you can watch as the values change based on scripts you've written.

The Director Debugger window displays this information also, but is only available when you are in debugging mode. For more information on debugging, see “Advanced debugging” on page 99.

Viewable objects

The following are some of the objects you can enter into the Object inspector:

- Sprites, such as sprite(3)
- Cast members, such as member("3d")
- Global variables, such as gMyList
- Child objects, such as gMyChild
- Macromedia Flash objects, such as gMyFlashObject; for more information about using Flash objects in Director, see the Using Director topics in the Director Help Panel.
- Script expressions, such as sprite(7).blend

Viewing objects

There are three ways to view an object in the Object inspector. You can drag items directly into the Object inspector, enter the name of an item into the Object inspector manually, or use the Inspect Object button in the Message and Script windows.

To drag an item to the Object inspector, do one of the following:

- Select a sprite in the Score window and drag it to the Object inspector.
- Select a cast member in the Cast window and drag it to the Object inspector.
- Select a the name of an object in the Script, Message, or Text window and drag it to the Object inspector.

To enter an object manually in the Object inspector:

1. Double-click in the first empty cell in the Object column of the Object inspector.
2. Type the name of the object into the cell. Use the same name you would use to refer to the object in your scripts.
3. Press Enter (Windows) or Return (Macintosh). If the object has subproperties, a plus sign (+) appears to the left of it.
4. Click the plus sign. The properties of the object appear below it. Properties with subproperties appear with a plus sign to their left. Click each plus sign to display the subproperties.
To view an object using the Inspect Object button:
1. In the Script window, highlight the part of a statement that refers to an object.
2. In the Script window, click Inspect Object. If the object has subproperties, a plus sign (+) appears to the left of it.
3. Click the plus sign. The properties of the object appear below it. Properties with subproperties appear with a plus sign to their left. Click each plus sign to display the subproperties.

Note: Inspecting large numbers of objects or large individual objects in the Object inspector can cause noticeable performance issues during authoring, particularly when Auto Poll is enabled. For example, inspecting a list that contains 10,000 entries can make Director appear to hang while the display is updating.

Navigating objects
You can also navigate the contents of the Object inspector with the arrow keys on your keyboard.

To move up or down in the list of items:
- Use the Up and Down arrow keys.

To view an item’s subproperties:
- Select the item and press the Right arrow key.

To hide an item’s subproperties:
- Select the item and press the Left arrow key.

Using Autopoll
System properties, such as milliseconds and colorDepth are only updated in the Object inspector when the Autopoll option is turned on. Using Autopoll increases the processor workload, which can slow your movie’s performance when you add more than a few system properties to the Object inspector.

To turn on Autopoll:
1. Right-click (Windows) or Control-click (Macintosh) in the Object inspector. The Object inspector context menu appears.
2. Select Autopoll from the context menu. When Autopoll is on, a check mark appears next to the Autopoll item in the context menu.

To turn off Autopoll:
- Select Autopoll from the context menu again.

Modifying object or property values
You can set the value of an object or property in the Object inspector by entering a new value in the box to the right of the object or property name.

To set an object or property value:
1. Double-click the value to the right of the item name.
2. Enter the new value for the item.
3. Press Enter (Windows) or Return (Macintosh). The new value is set and reflected in your movie immediately.

You can enter a script expression as the value for an item. For example, you might set the value of sprite(3).locH to the expression sprite(8).locH + 20.
Removing objects

You can also remove items from the Object inspector.

To remove a single item from the Object inspector:
• Select the item and press the Backspace (Windows) or Delete (Macintosh) key.

To clear the entire contents of the Object inspector:
• Right-click (Windows) or Control-click (Macintosh) inside the Object inspector and select Clear All from the context menu.

When you open a separate movie from the one you are working on, the objects you entered in the Object inspector remain. This makes it easy to compare different versions of the same movie. When you exit Director, the items in the Object inspector are lost.

Debugging in the Debugger window

The Debugger window is a special mode of the Script window. It provides several tools for finding the causes of problems in your scripts. By using the Debugger, you can quickly locate the parts of your code that are causing problems. The Debugger window allows you to run scripts one line at a time, skip over nested handlers, edit the text of scripts, and view the values of variables and other objects as they change. Learning to use the tools in the Debugger window can help you become a more efficient programmer.

The Debugger window can help you locate and correct errors in your scripts. It includes several tools that let you do the following:
• See the part of the script that includes the current line of code.
• Track the sequence of handlers that were called before getting to the current handler.
• Run selected parts of the current handler.
• Run selected parts of nested handlers called from the current handler.
• Display the value of any local variable, global variable, or property related to the code that you’re investigating.

Entering debugging mode

In order to access the Debugger window, a break must occur in a script. A break occurs when Director encounters a script error or a breakpoint in a script.

When a script error occurs, the Script Error dialog box appears. The dialog box displays information about the type of error that occurred, and asks you whether you want to debug the script, edit the script in the Script window, or cancel.

To enter debugging mode, do one of the following:
• Click Debug in the Script Error dialog box.
• Place a breakpoint in a script.

When Director runs and encounters a breakpoint, the script stops executing and the Script window changes to debugging mode. The movie is still playing, but the execution of your scripts is stopped until you use the Debugger to tell Director how to proceed. If you have multiple Script windows open, Director searches for one containing the script where the breakpoint occurred and changes that window to debugging mode.
To add a breakpoint that will open the Debugger window:

1. In the Script window, open the script that should contain the breakpoint.
2. Click in the left margin of the Script window next to the line of code where you want the breakpoint to appear, or place the insertion point on the line of code and click Toggle Breakpoint. Your code will stop executing at the beginning of this line, and the Script window will enter debugging mode.

If the Script window is open when Director encounters a script error or a breakpoint, the Debugger window replaces the Script window.

To stop debugging, do one of the following:

- Click the Run Script button in the Debugger window. This resumes normal script execution.
- Click the Stop Debugging button in the Debugger window. This stops both the debugging session and the movie.

The Script window reappears in place of the Debugger window.

When the Debugger window opens, it shows the current line of code and offers several choices for what to run next.

To see which is the current line of code:

- Look for the green arrow next to a line of code in the Script pane.

The green arrow points to the current line. You cannot select a different line of code by clicking it in the Script pane.

Viewing the call stack in the Debugger window

The Call Stack pane displays the sequence of nested handlers that ran before the current line of code. This sequence is called the call stack. Use the call stack to keep track of the structure of your code while you are debugging. You can view the variables associated with a specific handler by clicking the handler name in the Call Stack pane. The variables are displayed in the Variable pane.
Viewing variables in the Debugger window

The Variable pane of the Debugger window displays the variables associated with the current handler. The current handler is the handler displayed in the Script pane and the last handler displayed in the Call Stack pane. You can also display the variables associated with previous handlers in the call stack. As you step through a script, changes to the values of any of the variables are displayed in red. For more information on stepping through scripts, see “Stepping through scripts in the Debugger window” on page 97.

To display the variables associated with a handler in the call stack:

- Click the name of the handler in the Call Stack pane. The variables appear in the Variable pane.

The Variable pane includes four tabs for viewing variables:

- **The All tab** displays both global and local variables associated with the current handler.
- **The Local tab** displays only the local variables associated with the selected handler.
- **The Property tab** displays the properties declared by the current script.
- **The Global tab** displays only the global variables associated with the selected handler.

You can sort the variables in the Variable pane:

- To sort the variables by name, click the word Name that appears above the variable names.
- To sort the variables in reverse-alphabetical order, click the word Name a second time.

You can change the values of local variables of the current handler and global variables in the Variable pane. You cannot change the value of local variables that are not in the current handler.

To change the value of a variable in the Variable pane:

1. Double-click the value of the variable in the Value column.
2. Enter the new value for the variable.
3. Press Enter (Windows) or Return (Macintosh).

Viewing objects in the Debugger window

With the Watcher pane in the Debugger window, you can view variables and other data objects associated with the current handler, as well as objects associated with other handlers. By adding objects to the Watcher pane, you can keep track of their values as they change because of scripts. When the value of an object changes due to the execution of a line of code, Director changes the color of the object's name in the Watcher pane to red.

The Watcher pane displays only the objects you add to it. You can use up to four separate tabs in the Watcher pane to organize objects into groups.

To add an object to the Watcher pane whose name appears in the Script pane:

1. Select the name of the object in the Script pane.
2. Click the Watch Expression button.
To add an object to the Watcher pane whose name does not appear in the Script pane:
1 Double-click the first empty cell in the object column of the Watcher pane.
2 Type the name of the object in the cell and press Enter (Windows) or Return (Macintosh).
   If the object has properties, a plus sign (+) appears next to the object’s name.

To display an object’s properties:
• Click the plus sign next to the object name.

The Watcher pane lets you organize objects in a few ways.

To organize objects in the Watcher pane, do one of the following:
• To sort the objects in the Watcher pane, click the Name column head at the top of the left column. The object names in the column are listed in alphabetical order.
• To sort the objects in reverse-alphabetical order, click the Name column head a second time.
• To organize objects into groups, use the tabs in the Watcher pane. To add an object to a specific tab, click the tab you want to use before adding the object.
• To clear the contents of a tab in the Watcher pane, select the tab and then right-click (Windows) or Control-click (Macintosh) in the Watcher pane and select Clear All.

Stepping through scripts in the Debugger window

The Debugger window provides you with a set of tools for running scripts slowly, so you can watch the effect that each line of code has on your movie. You can execute one line of code at a time and choose whether to execute nested handlers one line at a time or all at once.

To execute only the current line of code indicated by the green arrow:
• Click the Step Script button.

Many handlers include calling statements to other handlers. You can focus your attention on such nested handlers, or ignore them and focus on the code in the current handler.

When you are confident that nested handlers are performing as expected and want to concentrate on the code in the current handler, the Debugger window can step over nested handlers and go directly to the next line of code in the current handler. When the Debugger steps over a nested handler, it executes the handler, but does not display the handler’s code or pause within the nested handler.

To step over nested handlers:
• Click the Step Script button in the Debugger window.

The Step Script button runs the current line of code, runs any nested handlers that the line calls, and then stops at the next line in the handler.

If you suspect that nested handlers are not performing as expected and want to study their behavior, the Debugger window can run nested handlers line by line as well.

To run nested handlers one line at a time:
• Click the Step Into Script button in the Debugger window.

Clicking the Step Into button runs the current line of code and follows the normal flow through any nested handlers called by that line. When finished with a nested handler, the Debugger window stops at the next line of code within the upper-level handler.
When you are finished debugging, you can exit the Debugger at any time:

**To resume normal execution of code an exit the Debugger window:**
- Click the Run Script button.

**To exit the Debugger and stop playback of the movie:**
- Click the Stop Debugging button.

### Editing scripts in debugging mode

When you are in debugging mode, you may edit your scripts directly in the Debugger window. This enables you to fix bugs as soon as you find them and then continue debugging.

**To edit a script in the Debugger window:**
1. Click in the Script pane and place the insertion point where you want to begin typing.
2. Enter the changes to the script.
   - You can jump to a specific handler by selecting the name of the handler and clicking the Go To Handler button.
3. When you are finished debugging and editing scripts, click the Stop Debugging button. The Script window returns to Script mode.
4. Click the Recompile All Modified Scripts button.

### Debugging projectors and Shockwave movies

This section discusses debugging during runtime in Director projectors and movies that contain Macromedia Shockwave content. You can use either the Message window or enable full script error dialog boxes to debug projectors and movies that contain Shockwave content.

**To debug using the Message window:**
- Set the Player object’s `debugPlaybackEnabled` property to `TRUE`.
  - When this property is `TRUE`, playing back a projector or a movie that contains Shockwave content opens a Message window (Windows) or a Message text file (Macintosh), and the results of any `put()` or `trace()` function calls are output to these formats.
  - If at any time during the movie the `debugPlaybackEnabled` property is set to `FALSE`, the Message window or text file is closed and cannot be opened again during that playback session, even if `debugPlaybackEnabled` is set back to `TRUE` later in that session.

**To debug by enabling full script error dialogs:**
- In an .ini file for a projector or a movie that contains Shockwave content, set the `DisplayFullLingoErrorText` property to 1.
  - This generates more descriptive error text in the script error dialog box than the generic error text. For example, a generic error message might look like:
    ```
    Script error: Continue?
    ```
  - Setting the `DisplayFullLingoErrorText` property to 1 could generate the following error message:
    ```
    Script error: list expected
    ```
  - For information on creating and modifying an appropriate .ini file for a projector or a movie that contains Shockwave content, see the Director.ini template file in the root Director installation folder.
Advanced debugging

If the problem is not easy to identify, try the following approaches:

- Determine which section has the problem. For example, if clicking a button produces the wrong result, investigate the script assigned to the button. If a sprite does the wrong thing, try checking the sprite's property values. Are they set to the values you want when you want?
- Figure out where the script flows. When a section of the movie does not do what you want, first try to trace the movie's sequence of events in your head. Look at other scripts in the message hierarchy to make sure Director is running the correct handler.
- Follow the tracing in the Message window; this shows which frames the movie goes through and any handlers that the movie calls as the movie plays.
- Try using the Step Script and Step Into features in the Debugger window and see whether the results differ from what you expect.
- Check variables and expressions. Analyze how their values change as the movie plays. See if they change at the wrong time or do not change at all. If the same variable is used in more than one handler, make sure that each handler that uses the variable states that the variable is global. You can track the values of variables and expressions by displaying their values in the Watcher pane of the Debugger window or the Object inspector.
- Make changes one at a time. Don't be afraid to change things in a handler to see if the change eliminates the problem or gives some result that helps point to the problem. However, do not trade one problem for another. Change things one at a time and change them back if the problem is not fixed. If you introduce too many changes before solving a problem, you might not determine what the original problem was and you might even introduce new problems.
- Re-create the section. If you have not found the problem, try re-creating the section from scratch. For example, if rolling the pointer over a sprite does not make the sprite behave the way you want, create a simple movie that contains just the sprite and handler with the `rollOver()` method. Do not just copy and paste scripts; that might just copy the problem. Re-creating the section lets you reconstruct the logic at its most basic level and verify that Director is working as you expect. If the section that you re-create still does not work properly, chances are that there is something wrong in the logic for the section.
- If the section that you re-create works properly, compare that section to the original movie to see where the two differ. You can also copy the section into the original piece and see whether this corrects the problem.
The core objects in Macromedia Director MX 2004 provide access to the core functionality and features available in Director, projectors, and the Macromedia Shockwave Player. Core objects include the Director player engine, movie windows, sprites, sounds, and so on. They represent the base layer through which almost all APIs and other object categories are accessed; the exceptions are the scripting objects, which extend the core functionality of Director.

For an illustration of how the core objects relate to each other and to other objects in Director, see “Object model diagrams” on page 53.

**Cast Library**

Represents a single cast library within a movie.

A movie can consist of one or more cast libraries. A cast library can consist of one or more cast members, which represent media in a movie, such as sounds, text, graphics, and other movies.

You can create a reference to a cast library by using either the top level `castLib()` function or the `Movie` object's `castLib` property. For example, if a movie contains a cast library named `scripts`, you could create a reference to this cast library by doing the following:

- Use the top level `castLib()` method.
  ```
  -- Lingo syntax
  libScript = castLib("scripts")
  
  // JavaScript syntax
  var libScript = castLib("scripts");
  ```

- Use the `Movie` object's `castLib` property.
  ```
  -- Lingo syntax
  libScript = _movie.castLib["scripts"]
  
  // JavaScript syntax
  var libScript = _movie.castLib["scripts"];
  ```

castLib, castLib(), Member, Movie, Player, Sprite, Window

Global

Provides a location to store and access global variables. These variables are available to both Lingo and JavaScript syntax.

You can access the Global object by using the top level _global property. You can either assign _global to a variable, or use the _global property directly to access the Global object's methods and any defined global variables.

• Assign _global to a variable.
  -- Lingo syntax
  objGlobal = _global
  // JavaScript syntax
  var objGlobal = _global;

• Use the _global property directly.
  -- Lingo syntax
  _global.showGlobals();
  // JavaScript syntax
  _global.showGlobals();

• Access a global variable.
  -- Lingo syntax
  global gSuccess
  on mouseDown
    gSuccess = "Congratulations!"
    put(gSuccess) -- displays "Congratulations!"
  end
  // JavaScript syntax
  _global.gSuccess = "Congratulations!":
  function mouseDown(){
    trace(_global.gSuccess); // displays "Congratulations!"
  }

_key

Key

Used to monitor a user’s keyboard activity.

You can access the Key object by using the top level _key property. You can either assign _key to a variable, or use the _key property directly to access the Key object’s methods and properties.

• Assign _key to a variable.
  -- Lingo syntax
  objKey = _key
  // JavaScript syntax
  var objKey = _key;

• Use the _key property directly.
  -- Lingo syntax
  isCtrlDown = _key.controlDown
  // JavaScript syntax
  var isCtrlDown = _key.controlDown;

_key
Member

Represents a cast member within a cast library. Cast members are the media and script assets in a movie. Media cast members may be text, bitmaps, shapes, and so on. Script cast members include behaviors, movie scripts, and so on.

A cast member can be referenced either by number or by name.

• When referring to a cast member by number, Director searches a particular cast library for that cast member, and retrieves the member's data. This method is faster than referring to a cast member by name. However, because Director does not automatically update references to cast member numbers in script, a numbered reference to a cast member that has moved position in its cast library will be broken.

• When referring to a cast member by name, Director searches all cast libraries in a movie from first to last, and retrieves the member's data when it finds the named member. This method is slower than referring to a cast member by number, especially when referring to large movies that contain many cast libraries and cast members. However, a named reference to a cast member allows the reference to remain intact even if the cast member moves position in its cast library.

You can create a reference to a cast member by using either the top level member() function, or by using the member property of the Cast, Movie, or Sprite object.

The following examples illustrate creating a reference to a cast member.

• Use the top level member() function.
  -- Lingo syntax
  objTree = member("bmpTree")
  
  // JavaScript syntax
  var objTree = member("bmpTree");

• Use the Sprite object's member property.
  -- Lingo syntax
  objTree = sprite(1).member;
  
  // JavaScript syntax
  var objTree = sprite(1).member;

</tr>
</tbody>
</table>
**Mouse**

Provides access to a user’s mouse activity, including mouse movement and mouse clicks.

You can access the Mouse object by using the top level _mouse property. You can either assign _mouse to a variable, or use the _mouse property directly to access the Mouse object’s properties.

- **Assign _mouse to a variable.**
  
  -- Lingo syntax
  objMouse = _mouse

  // JavaScript syntax
  var objMouse = _mouse;

- **Use the _mouse property directly.**
  
  -- Lingo syntax
  isDbClick = _mouse.doubleClick

  // JavaScript syntax
  var isDbClick = _mouse.doubleClick;

`_mouse`

Movie

Represents a movie being played within the Director player.

The Director player can contain one or more movies. A movie can consist of one or more cast libraries. A cast library can consist of one or more cast members, which represent the media and script assets in a movie. Media cast members may be text, bitmaps, shapes, and so on. Script cast members include behaviors, movie scripts, and so on. Sprites are created from cast members and are used on the Stage of a movie.

You can refer to the currently active movie by using the top level `_movie` property. You can refer to any movie in the player by using the Window object's `movie` property.

- Refer to the currently active movie.
  ```
  // Lingo syntax
  objMovie = _movie
  // JavaScript syntax
  var objMovie = _movie;
  ```

- Use the Window object's `movie` property to access the movie in a particular window.
  ```
  // Lingo syntax
  objMovie = _player.window[2].movie
  // JavaScript syntax
  var objMovie = _player.window[2].movie;
  ```

In Director MX 2004, you can use a movie reference to access not only the methods and properties of a movie itself, you can also call Lingo and JavaScript syntax handlers, and access the movie's cast members and sprites, including their methods and properties. This differs from previous versions of Director in which you had to use the `tell` command to work with movies. The Movie object provides a simpler way to work with movies.

*Note:* The `tell` command is obsolete in Director MX 2004.

Player

Represents the core playback engine used to manage and execute the authoring environment, movies in a window (MIAWs), projectors, and Shockwave Player.

The Player object provides access to all of the movies and windows that it is managing, in addition to any Xtra extensions that are available.

You can create a reference to the Player object by using the top level _player property.

• Assign _player to a variable.
  -- Lingo syntax
  objPlayer = _player
  // JavaScript syntax
  var objPlayer = _player;

• Use the _player property directly.
  -- Lingo syntax
  _player.alert("The movie has ended.")
  // JavaScript syntax
  _player.alert("The movie has ended.");

Sound

Controls audio playback in all eight available sound channels.

The Sound object consists of Sound Channel objects, which represent individual sound channels.

You can create a reference to the Sound object by using top level _sound property.

- Assign _sound to a variable.
  -- Lingo syntax
  objSound = _sound

  // JavaScript syntax
  var objSound = _sound;

- Use the _sound property to access the Sound object's soundDevice property.
  -- Lingo syntax
  objDevice = _sound.soundDevice

  // JavaScript syntax
  var objDevice = _sound.soundDevice;

-_sound, Sound Channel
**Sound Channel**

Represents an individual sound channel found within the Sound object.

There are eight available sound channels. You can use a Sound Channel object in script to access and modify any of the eight sound channels.

**Note:** You can modify only the first two sound channels in the Score of the Director user interface.

You can create a reference to a Sound Channel object by using the top level `sound()` method, the Player object's `sound` property, or the Sound object's `channel()` method. For example, you can reference sound channel 2 by doing the following:

- **Use the top level sound() method.**
  -- Lingo syntax
  objSoundChannel = sound(2)
  // JavaScript syntax
  var objSoundChannel = sound(2);

- **Use the Player object's sound property.**
  -- Lingo syntax
  objSoundChannel = _player.sound[2]
  // JavaScript syntax
  var objSoundChannel = _player.sound[2];

- **Use the Sound object's channel() method.**
  -- Lingo syntax
  objSoundChannel = _sound.channel(2)
  // JavaScript syntax
  var objSoundChannel = _sound.channel(2);

channel() (Sound), sound (Player), sound(), Sound

Sprite

Represents an occurrence of a cast member in a sprite channel of the Score.

A Sprite object covers a sprite span, which is a range of frames in a given sprite channel. A Sprite Channel object represents an entire sprite channel, regardless of the number of sprites it contains.

A sprite can be referenced either by number or by name.

• When referring to a sprite by number, Director searches all sprites that exist in the current frame of the Score, starting from the lowest numbered channel, and retrieves the sprite's data when it finds the numbered sprite. This method is faster than referring to a sprite by name. However, because Director does not automatically update references to sprite numbers in script, a numbered reference to a sprite that has moved position on the Stage will be broken.

• When referring to a sprite by name, Director searches all sprites that exist in the current frame of the Score, starting from the lowest numbered channel, and retrieves the sprite's data when it finds the named sprite. This method is slower than referring to a sprite by number, especially when referring to large movies that contain many cast libraries, cast members, and sprites. However, a named reference to a sprite allows the reference to remain intact even if the sprite moves position on the Stage.

You can create a reference to a Sprite object by using the top level sprite() function, the Movie object's sprite property, or the Sprite Channel object's sprite property.

• Use the top level sprite() function.
  -- Lingo syntax
  objSprite = sprite(1)
  // JavaScript syntax
  var objSprite = sprite(1);

• Use the Movie object's sprite property.
  -- Lingo syntax
  objSprite = _movie.sprite["willowTree"]
  // JavaScript syntax
  var objSprite = _movie.sprite["willowTree"];[384]

• Use the Sprite Channel object's sprite property.
  -- Lingo syntax
  objSprite = channel(3).sprite
  // JavaScript syntax
  var objSprite = channel(3).sprite;
You can use a reference to a Sprite object to access the cast member from which the sprite was created. Any changes made to the cast member from which a sprite was created are also reflected in the sprite. The following example illustrates changing the text of a text cast member from which sprite 5 was created. This change to the cast member will also be reflected in sprite 5.

-- Lingo syntax
labelText = sprite(5)
labelText.member.text = "Weeping Willow"

// JavaScript syntax
var labelText = sprite(5);
labelText.member.text = "Weeping Willow";

Sprite Channel

Represents an individual sprite channel in the Score.

A Sprite object covers a sprite span, which is a range of frames in a given sprite channel. A Sprite Channel object represents an entire sprite channel, regardless of the number of sprites it contains.

Sprite channels are controlled by the Score by default. Use the Sprite Channel object to switch control of a sprite channel over to script during a Score recording session.

A sprite channel can be referenced either by number or by name.

- When referring to a sprite channel by number, you access the channel directly. This method is faster than referring to a sprite channel by name. However, because Director does not automatically update references to sprite channel numbers in script, a numbered reference to a sprite channel that has moved position in the Score will be broken.
- When referring to a sprite channel by name, Director searches all channels, starting from the lowest numbered channel, and retrieves the sprite channel's data when it finds the named sprite channel. This method is slower than referring to a sprite channel by number, especially when referring to large movies that contain many cast libraries, cast members, and sprites. However, a named reference to a sprite channel allows the reference to remain intact even if the sprite channel moves position in the Score.

You can create a reference to a Sprite Channel object by using the top level `channel()` method, and referring to either the channel number or name.

-- Lingo syntax
```lingo
objSpriteChannel = channel(2) -- numbered reference
objSpriteChannel = channel("background") -- named reference
```

// JavaScript syntax
```javascript
var objSpriteChannel = channel(2); // numbered reference
var objSpriteChannel = channel("background"); // named reference
```

You can use a reference to a Sprite Channel object to access the sprite that is currently being used in a particular sprite channel. The following example illustrates accessing the background color of the sprite that is currently being used in sprite channel 2.

-- Lingo syntax
```lingo
labelSprite = channel(2).sprite.backColor
```

// JavaScript syntax
```javascript
var labelSprite = channel(2).sprite.backColor;
```

*Cast Library, channel() (Top Level), Member, Movie, Player, Sprite, Window*

**System**

Provides access to system and environment information, including system level methods.

You can create a reference to the System object by using the top level _system property.

- **Assign _system to a variable.**
  -- Lingo syntax
  objSystem = _system
  // JavaScript syntax
  var objSystem = _system;

- **Use the _system property directly.**
  -- Lingo syntax
  sysDate = _system.date()
  // JavaScript syntax
  var sysDate = _system.date();

*_system*
Window

Represents a window in which a movie is playing, including the Stage window and any other movies in a window (MIAWs) that are in use.

You can create a reference to a Window object by using the top level `window()` function, the Player object’s `window` property, or the Player object’s `windowList` property.

- Use the top level `window()` method.
  -- Lingo syntax
  `objWindow = window("Sun")`
  // JavaScript syntax
  `var objWindow = window("Sun");`

- Use the Player object’s `window` property.
  -- Lingo syntax
  `objWindow = _player.window["Sun"]`
  // JavaScript syntax
  `var objWindow = _player.window["Sun"];`

- Use the Player object’s `windowList` property.
  -- Lingo syntax
  `objWindow = _player.windowList[1]`
  // JavaScript syntax
  `var objWindow = _player.windowList[1];`

**Note:** When creating a named reference to a window by using either the top level `window()` function or the Player object’s `window` property, a reference to that window is created only if a window by that name exists. If a window by that name does not exist, the reference contains `VOID` (Lingo) or `null` (JavaScript syntax).

### Method summary for the Window object

CHAPTER 6
Media Types

The media types in Macromedia Director MX 2004 provide access to the functionality of the various media types, such as RealMedia, DVD, Animated GIF, and so on, that are added to movies as cast members.

Literally, media types are not actually objects, but rather cast members that are of a specific type of media. When a media type is added to a movie as a cast member, it not only inherits the functionality of the core Member object, it also extends the Member object by providing additional functionality that is available only to the specified media type. For example, a RealMedia cast member has access to the Member object’s methods and properties, but it also has additional methods and properties that are specific to RealMedia. All other media types also exhibit this behavior.

For an illustration of how the cast member media types relate to each other and to other objects in Director, see “Object model diagrams” on page 53.

Animated GIF

Represents an animated GIF cast member.

You can add an animated GIF cast member to a movie by using the Movie object’s newMember() method.

-- Lingo syntax
_movie.newMember(#animgif)

// JavaScript syntax
_movie.newMember("animgif");

Some of the following methods or properties may apply only to sprites that are created from an animated GIF cast member.
### Method summary for the Animated GIF media type

<table>

- Member

**Bitmap**

Represents a bitmap cast member.

You can use bitmap image objects to perform simple operations that affect the content of an entire bitmap cast member, such as changing the background and foreground colors of the member, or to perform fine manipulations of the pixels of an image, such as cropping, drawing, and copying pixels.

You can add a bitmap cast member to a movie by using the Movie object's newMember() method.

--- Lingo syntax

```
_movie.newMember(#bitmap)
```

--- JavaScript syntax

```
_movie.newMember("bitmap");
```

Some of the following methods or properties may apply only to sprites that are created from a bitmap cast member.

### Method summary for the Bitmap media type

<table>
<thead>
<tr>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>crop()</td>
</tr>
<tr>
<td>picture()</td>

See also

Member

Button

Represents a button or check box cast member.

You can add a button cast member to a movie by using the Movie object's newMember() method.

-- Lingo syntax
_movie.newMember(#button)

// JavaScript syntax
_movie.newMember("button");

Property summary for the Button media type

<table>
<thead>
<tr>
<th>Property</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>hilite</td>
<td></td>
</tr>
</tbody>
</table>

Member

Color Palette

Represents the color palette associated with a bitmap cast member.

A color palette cast member does not have any methods or properties that can be accessed directly from it. The following methods and properties are merely associated with color palettes.

You can add a color palette cast member to a movie by using the Movie object’s newMember() method.

-- Lingo syntax
_movie.newMember(#palette)

// JavaScript syntax
_movie.newMember("palette");
You can associate a bitmap cast member with a color palette cast member by setting the `palette` property of the bitmap cast member. The following example sets the `palette` property of the bitmap cast member `bmpMember` to the color palette cast member `colorPaletteMember`. The value of the `palette` property reflects the number of the color palette cast member.

```-- Lingo syntax
member("bmpMember").palette = member("colorPaletteMember")
```

```// JavaScript syntax
member("bmpMember").palette = member("colorPaletteMember");
```

After you associate a bitmap cast member with a color palette cast member, you cannot delete the color palette cast member until you remove its association with the bitmap cast member.

**DVD**

Represents a DVD cast member.

You can add a DVD cast member to a movie by using the Movie object’s `newMember()` method.

--- Lingo syntax
_movie.newMember(#dvd)

// JavaScript syntax
_movie.newMember("dvd");

Some of the following methods or properties may apply only to sprites that are created from a DVD cast member.

**Event summary for the DVD media type**

The following DVD events are always be handled by a `DVDeventNotification` event handler. When one of these events occurs, the `DVDeventNotification` event handler receives the event as a parameter. Some of these events also contain additional information that is passed as a second or third parameter to `DVDeventNotification`. For more information on using the following events with the `DVDeventNotification` handler, see “on DVDeventNotification” on page 165.

<table>

Member

**Flash Component**

Represents a Macromedia Flash component that is embedded in a cast member or sprite that contains Flash content.

A Flash component provides prepackaged functionality that extends the existing functionality of cast members or sprites that contain Flash content. They are created and supported entirely by the Director development community.
Director supports the following Flash components:

<table>
<thead>
<tr>
<th>Flash component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Button</td>
<td>A resizable rectangular user interface button.</td>
</tr>
<tr>
<td>CheckBox</td>
<td>A fundamental part of any form or web application; can be used wherever you need to gather a set of true or false values that aren’t mutually exclusive.</td>
</tr>
<tr>

<td>A multiline text field.</td>
</tr>
<tr>
<td>TextInput</td>
<td>A single-line component that wraps the native ActionScript TextField object.</td>
</tr>
<tr>
<td>Tree</td>
<td>Allows a user to view hierarchical data.</td>
</tr>
</tbody>
</table>

A Flash component has access to the same APIs that a regular Flash cast member or sprite does, in addition to the functionality that is specific to that component. For more information about using these Flash components, see the Using Director topics in the Director Help Panel.

You can add a Flash component cast member to a movie by using the Movie object’s newMember() method.

-- Lingo syntax
_movie.newMember(#flashcomponent)

// JavaScript syntax
_movie.newMember("flashcomponent");

Flash Movie, Member
Flash Movie

Represents a cast member or sprite that contains Flash content.

You can add a Flash movie cast member to a movie by using the Movie object’s `newMember()` method.

```lingo
_movie.newMember(#flash)
```

```javascript
_movie.newMember("flash");
```

A Flash movie cast member or sprite can also contain Flash components. Flash components provide prepackaged functionality that extends the existing functionality of Flash movie cast members or sprites. For more information about the Flash components that Director supports, see "Flash Component" on page 125.

Some of the following methods or properties may apply only to sprites that are created from a Flash movie cast member.

Sound

Represents a cast member that is used to store and refer to sound samples.

Sound samples are controlled by the core Sound and Sound Channel objects. A sound cast member does not have any APIs of its own, and uses the APIs of the Sound and Sound Channel objects to control its behavior.

You can add a sound cast member to a movie by using the Movie object’s `newMember()` method.

-- Lingo syntax
_movie.newMember(#sound)

// JavaScript syntax
_movie.newMember("sound");

For more information on the objects and APIs you can use to control sound samples, see “Sound” on page 110 and “Sound Channel” on page 111.

The scripting objects, also known as Xtra extensions, in Macromedia Director MX 2004 provide access to the functionality of the software components that are installed with Director and extend core Director functionality. The preexisting Xtra extensions provide capabilities such as importing filters and connecting to the Internet. If you know the C programming language, you can create your own custom Xtra extensions.

For an illustration of how the scripting objects relate to each other and to other objects in Director, see “Object model diagrams” on page 53.

**Fileio**

Enables you to perform file input and output operations.

You can create a reference to a Fileio object by using the `new` operator.

-- Lingo syntax
```lingo
objFileio = new xtra("fileio")
```

// JavaScript syntax
```javascript
var objFileio = new xtra("fileio");
```

**Method summary for the Fileio object**

<table>
<thead>
<tr>
<th>Method</th>
<th>Method</th>

</tr>
</tbody>
</table>
The 3D objects enable you to add 3D functionality to a movie. These objects are exposed to both Lingo and JavaScript syntax within Macromedia Director MX 2004, projectors, and the Macromedia Shockwave Player.

You access these 3D objects through Shockwave 3D (or simply 3D) cast members. You can also create 3D sprites from the 3D cast members. Both 3D cast members and 3D sprites contain functionality that is specific to 3D cast members and sprites. They also have access to the functionality of non-3D cast members and sprites, whose APIs are specified by the core Member and Sprite objects, respectively.

A 3D cast member differs from a non-3D cast member in that a 3D cast member contains a complete 3D world. A 3D world contains the objects that provide access to 3D functionality. All objects in a 3D world are based on a basic object known as a node. The simplest form of a node in a 3D world is a Group object; a Group object is essentially the most basic node. All other objects in a 3D world are based on a Group object, which means that the other objects inherit the functionality of a Group object in addition to containing functionality that is specific to those objects.

For an illustration of how the 3D objects relate to each other and to other objects in Director, see “Object model diagrams” on page 53.

Director ships with two Xtra extensions that enable access to the 3D objects:

- 3D Asset Xtra (3DAuth.x32 in Windows, 3D Auth Xtra on Macintosh) provides support for the 3D media window inside Director.
- 3D Media Xtra (Shockwave 3D Asset.x32 in Windows, 3D Asset Xtra on Macintosh) provides support for the 3D media itself.

To access the 3D objects during authoring or at runtime, your movie must contain the 3D Asset Xtra.
**Camera**

Represents a Camera object.

A camera controls how a 3D sprite views the 3D world. A 3D sprite displays a particular camera's view into the world.

You can create a reference to a camera by using the `camera` property of the 3D Member object. The `camera` property gets the camera at a specified index position in the list of cameras. In Lingo, you use the `camera` property directly from the 3D Member object to create a reference. In JavaScript syntax, you must use the `getPropRef()` method to create a reference.

The following example creates a reference to the second camera of the 3D cast member "family room", and assigns it to the variable `myCamera`.

```-- Lingo syntax
myCamera = member("family room").camera[2]
// JavaScript syntax
var myCamera = member("family room").getPropRef("camera", 2);
```

**Method summary for the Camera object**

<table>

</tr>
<tr>
<td>overlay[].scale (3D)</td>
</tr>
<tr>
<td>overlay[].source</td>
</tr>
<tr>
<td>overlay.count (3D)</td>
</tr>
</tbody>
</table>
Group

Represents a model that does not have a resource or any shaders.

A group is the most basic node, and is merely a point in space that is represented by a transform. You can assign children and parents to this node in order to group models, lights, cameras, or other groups.

The most basic group is called a world, which is essentially synonymous with a 3D cast member.

You can create a reference to a group by using the group property of the 3D Member object. The group property gets the group at a specified index position in the list of groups. In Lingo, you use the group property directly from the 3D Member object to create a reference. In JavaScript syntax, you must use the getPropRef() method to create a reference.

The following example creates a reference to the first group of the 3D cast member space, and assigns it to the variable myGroup.

```
-- Lingo syntax
myGroup = member("space").group[1]

// JavaScript syntax
var myGroup = member("space").getPropRef("group", 1);
```

Light

Represents a light in a 3D world.

Lights are used to light a 3D world. Without lights, the objects within the world cannot be seen. You can create a reference to a light by using the light property of the 3D Member object. The light property gets the light at a specified index position in the list of lights. In Lingo, you use the light property directly from the 3D Member object to create a reference. In JavaScript syntax, you must use the getPropRef() method to create a reference.

The following example creates a reference to the third light of the 3D cast member "film room" and assigns it to the variable myLight.

-- Lingo syntax
myLight = member("film room").light[3]

// JavaScript syntax
var myLight = member("film room").getPropRef("light", 3);

Member

Represents a Shockwave 3D cast member.

A Shockwave 3D (or simply 3D) cast member contains a complete 3D world. A 3D world contains the set of objects you use to add 3D functionality to a movie.

You can create a reference to a 3D cast member by using either the top level member() function, or by using the member property of the Movie or Sprite object. These are the same techniques you can use to create a reference to a non-3D cast member.

• Use the top level member() function.
  -- Lingo syntax
  3dMember = member("magic")

  // JavaScript syntax
  var 3dMember = member("magic");

• Use the Sprite object's member property.
  -- Lingo syntax
  3dMember = sprite(1).member;

  // JavaScript syntax
  var 3dMember = sprite(1).member;

Model

Represents a visible object that a user sees within a 3D world.

A model makes use of a model resource and occupies a specific position and orientation with a 3D world. A model resource is an element of 3D geometry that can be used to draw 3D models. A model also defines the appearance of the model resource, such as what textures and shaders are used. For more information about the relationship between models and model resources, see the Using Director topics in the Director Help Panel.

You can create a reference to a model by using the `model` property of the 3D `Member` object. The `model` property gets the model at a specified index position in the list of models. In Lingo, you use the `model` property directly from the 3D `Member` object to create a reference. In JavaScript syntax, you must use the `getPropRef()` method to create a reference.

The following example creates a reference to the second model of the 3D cast member `Transportation` and assigns it to the variable `myModel`.

-- Lingo syntax
myModel = member("Transportation").model[2]

// JavaScript syntax
var myModel = member("Transportation").getPropRef("model", 2):
A model also contains modifiers that control how the model is rendered or how its animation behaves. Modifiers are attached to a model by using the `addModifier()` method. After a modifier has been attached to a model, its properties can be manipulated with script.

The following modifiers are available to a model:

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bones player</td>
<td>Modifies a model’s geometry over time.</td>
</tr>
<tr>
<td>Collision</td>
<td>Allows a model to be notified of and respond to collisions.</td>
</tr>
<tr>
<td>Inker</td>
<td>Adds silhouette, crease, and boundary edges to an existing model.</td>
</tr>
<tr>
<td>Keyframe player</td>
<td>Modifies a model’s transform properties over time.</td>
</tr>
<tr>
<td>Level of detail (LOD)</td>
<td>Provides per-model control over the number of polygons used to render a model, based on the model's distance from a camera. The LOD modifier is also available to model resources.</td>
</tr>
<tr>
<td>Mesh deform</td>
<td>Alters an existing model resource’s geometry at runtime.</td>
</tr>
<tr>
<td>Subdivision surfaces (SDS)</td>
<td>Causes the model to be rendered with additional geometric detail in the area of the model that the camera is currently looking at.</td>
</tr>
<tr>
<td>Toon</td>
<td>Changes a model's rendering to imitate a cartoon drawing style.</td>
</tr>
</tbody>
</table>

For more information about the methods, properties, and events available to the modifiers, see the Using Director topics in the Director Help Panel.

**Model Resource**

Represents an element of 3D geometry that is used to draw 3D models.

A model makes use of a model resource and occupies a specific position and orientation with a 3D world. A model also defines the appearance of the model resource, such as what textures and shaders are used.

For more information about the relationship between models and model resources, and about using models and model resources, see the Using Director topics in the Director Help Panel.

You can create a reference to a model resource by using the `modelResource` property of the 3D Member object. The `modelResource` property gets the model resource at a specified index position in the list of model resources. In Lingo, you use the `modelResource` property directly from the 3D Member object to create a reference. In JavaScript syntax, you must use the `getPropRef()` method to create a reference.

The following example creates a reference to the second model resource of the 3D cast member wheels and assigns it to the variable `myModelResource`.

-- Lingo syntax  
myModelResource = member("wheels").modelResource[2]

// JavaScript syntax  
var myModelResource = member("wheels").getPropRef("modelResource", 2);
Motion

Represents a predefined animation sequence that involve the movement of a model or a model component.

Individual motions can be set to play by themselves or with other motions. For example, a running motion can be combined with a jumping motion to simulate a person jumping over a puddle.

You can create a reference to a motion by using the `motion` property of the 3D Member object. The `motion` property gets the motion at a specified index position in the list of motions. In Lingo, you use the `motion` property directly from the 3D Member object to create a reference. In JavaScript syntax, you must use the `getPropRef()` method to create a reference.

The following example creates a reference to the fourth motion of the 3D cast member `athlete` and assigns it to the variable `myMotion`.

```-- Lingo syntax
myMotion = member("athlete").motion[4]
// JavaScript syntax
var myMotion = member("athlete").getPropRef("motion", 4);
```

Renderer Services

Represents the global object that contains a property list whose values impact common rendering properties for all 3D cast members and sprites.

You can access the global renderer services object using the top level `getRendererServices()` function.

The following example accesses the renderer property of the global renderer services object and assigns the value to the variable `myRenderer`.

```-- Lingo syntax
myRenderer = getRendererServices().renderer
// JavaScript syntax
var myRenderer = getRendererServices().renderer;
```

Member, Sprite

Shader

Represents a model’s surface color.
You can draw images on the surface of a model by applying one or more textures to each shader.
You can create a reference to a shader by using the shader property of the 3D Member object. The shader property gets the shader at a specified index position in the list of shaders. In Lingo, you use the shader property directly from the 3D Member object to create a reference. In JavaScript syntax, you must use the getPropRef() method to create a reference.
The following example creates a reference to the second shader of the 3D cast member triangle and assigns it to the variable myShader.

-- Lingo syntax
myShader = member("triangle").shader[2]

// JavaScript syntax
var myShader = member("triangle").getPropRef("shader", 2);

Sprite

Represents a 3D sprite created from a Shockwave 3D cast member.
You can create a reference to a 3D sprite by using the top level sprite() function, the Movie object’s sprite property, or the Sprite Channel object’s sprite property. These are the same techniques you can use to create a reference to a non-3D sprite.

• Use the top level sprite() function.
  -- Lingo syntax
  3dSprite = sprite(1)

  // JavaScript syntax
  var 3dSprite = sprite(1);

• Use the Movie object’s sprite property.
  -- Lingo syntax
  3dSprite = _movie.sprite["willowTree"]

  // JavaScript syntax
  var 3dSprite = _movie.sprite["willowTree"];

• Use the Sprite Channel object’s sprite property.
  -- Lingo syntax
  3dSprite = channel(3).sprite

  // JavaScript syntax
  var 3dSprite = channel(3).sprite;
### Method summary for the Sprite object

Camera, Member

### Texture

Represents the texture applied to a shader.

You can create a reference to a texture by using the `texture` property of the 3D `Member` object. The `texture` property gets the texture at a specified index position in the list of textures. In Lingo, you use the `texture` property directly from the 3D `Member` object to create a reference. In JavaScript syntax, you must use the `getPropRef()` method to create a reference.

The following example creates a reference to the first texture of the 3D cast member `triangle` and assigns it to the variable `myTexture`.

-- Lingo syntax
myTexture = member("triangle").texture[1]

// JavaScript syntax
var myTexture = member("triangle").getPropRef("texture", 1);
CHAPTER 9
Constants

This section provides an alphabetical list of all the constants available in Macromedia Director MX 2004.

The majority of these constants apply only to Lingo. JavaScript syntax does contain some constants that are similar to the Lingo constants listed here; therefore, where appropriate, JavaScript syntax usage and examples are provided to help you map the functionality of Lingo constants with their closest counterparts in JavaScript syntax. For more information about JavaScript syntax constants, see one of the many third-party resources on the subject.

" (string)

Usage
---Lingo syntax
"

// JavaScript syntax
"

Description
String constant; when used before and after a string, quotation marks indicate that the string is a literal—not a variable, numerical value, or script element. Quotation marks must always surround literal names of cast members, casts, windows, and external files.

Example
This statement uses quotation marks to indicate that the string “San Francisco” is a literal string, the name of a cast member:

---Lingo syntax
put member("San Francisco").loaded

// JavaScript syntax
put(member("San Francisco").loaded);

See also
QUOTE
**BACKSPACE**

Usage
-- Lingo syntax
BACKSPACE

// JavaScript syntax
51 // value of _key.keyCode

Description
Constant; represents the Backspace key. This key is labeled Backspace in Windows and Delete on the Macintosh.

Example
This on keyDown handler checks whether the Backspace key was pressed and, if it was, calls the handler clearEntry:
-- Lingo syntax
on keyDown
  if (_key.key = BACKSPACE) then clearEntry
  _movie.stopEvent()
end keyDown

// JavaScript syntax
function keyDown() {
  if (_key.keyCode == 51) {
    clearEntry();
    _movie.stopEvent();
  }
}

**EMPTY**

Usage
-- Lingo syntax
EMPTY

// JavaScript syntax
"

Description
Character constant; represents the empty string, "", a string with no characters.

Example
This statement erases all characters in the field cast member Notice by setting the field to EMPTY:
-- Lingo syntax
member("Notice").text = EMPTY

// JavaScript syntax
member("Notice").text = "";
ENTER

Usage
--Lingo syntax
ENTER

// JavaScript syntax
3 // value of _key.keyCode

Description
Character constant; represents Enter (Windows) or Return (Macintosh) for a carriage return.
On PC keyboards, the element ENTER refers only to Enter on the numeric keypad.
For a movie that plays back as an applet, use RETURN to specify both Return in Windows and Enter on the Macintosh.

Example
This statement checks whether Enter is pressed and if it is, sends the playhead to the frame addSum:
-- Lingo syntax
on keyDown
  if (_key.key = ENTER) then _movie.go("addSum")
end

// JavaScript syntax
function keyDown() {
  if (_key.keyCode == 3) {
    _movie.go("addSum");
  }
}

See also
RETURN (constant)
FALSE

Usage
-- Lingo syntax
FALSE

// JavaScript syntax
false

Description
Constant; applies to an expression that is logically FALSE, such as 2 > 3. When treated as a
number value, FALSE has the numerical value of 0. Conversely, 0 is treated as FALSE.

Example
This statement turns off the soundEnabled property by setting it to FALSE:
-- Lingo syntax
_sound.soundEnabled = FALSE

// JavaScript syntax
_sound.soundEnabled = false;

See also
if, not, TRUE

PI

Usage
-- Lingo syntax
PI

// JavaScript syntax
Math.PI

Description
Constant; returns the value of pi (π), the ratio of a circle's circumference to its diameter, as a
floating-point number. The value is rounded to the number of decimal places set by the
floatPrecision property.

Example
This statement uses the PI constant as part of an equation for calculating the area of a circle:
-- Lingo syntax
vRadius = 3
vArea = PI*power(vRadius, 2)
trace(vArea) -- results in 28.2743

// JavaScript syntax
var vRadius = 3;
vArea = Math.PI*Math.pow(vRadius, 2);
trace(vArea); // results in 28.274333882308138
QUOTE

Usage
--Lingo syntax
QUOTE

// JavaScript syntax
""

Description
Constant; represents the quotation mark character and refers to the literal quotation mark character in a string, because the quotation mark character itself is used by Lingo scripts to delimit strings.

Example
This statement inserts quotation mark characters in a string:
-- Lingo syntax
put("Can you spell" && QUOTE & "Macromedia" & QUOTE & "?")

// JavaScript syntax
put("Can you spell "Macromedia"?");
The result is a set of quotation marks around the word Macromedia:
Can you spell "Macromedia"?
RETURN (constant)

Usage
-- Lingo syntax
RETURN

// JavaScript syntax
36 // value of _key.keyCode
\n // when used in a string

Description
Constant; represents a carriage return.

Example
This statement causes a paused movie to continue when the user presses the carriage return:

-- Lingo syntax
if (_key.key = RETURN) then _movie.go(_movie.frame + 1)

// JavaScript syntax
if (_key.keyCode == 36) {
    _movie.go(_movie.frame + 1);
}

This statement uses the RETURN character constant to insert a carriage return between two lines in an alert message:

-- Lingo syntax
_player.alert("Last line in the file." & RETURN & "Click OK to exit.")

// JavaScript syntax
_player.alert("Last line in the file.
Click OK to exit");

In Windows, it is standard practice to place an additional line-feed character at the end of each line. This statement creates a two-character string named CRLF that provides the additional line feed:

CRLF = RETURN & numToChar(10)

SPACE

Usage
-- Lingo syntax
SPACE

// JavaScript syntax
49 // value of _key.keyCode

Description
Constant; read-only, value that represents the space character.

Example
This statement displays “Age Of Aquarius” in the Message window:

-- Lingo syntax
put("Age"&SPACE&"Of"&SPACE&"Aquarius")
TAB

Usage
-- Lingo syntax
TAB

// JavaScript syntax
48 // value of _key.keyCode

Description
Constant; represents the Tab key.

Example
This statement checks whether the character typed is the tab character and calls the handler doNextField if it is:
-- Lingo syntax
if (_key.key = TAB) then doNextField

// JavaScript syntax
if (_key.keyCode == 48) {
    doNextField();
}

These statements move the playhead forward or backward, depending on whether the user presses Tab or Shift+Tab:
-- Lingo syntax
if (_key.key = TAB) then
    if (_key.shiftDown) then
        _movie.go(_movie.frame - 1)
    else
        _movie.go(_movie.frame + 1)
    end if
end if

// JavaScript syntax
if (_key.keyCode == 48) {
    if (_key.shiftDown) {
        _movie.go(_movie.frame - 1);
    } else {
        _movie.go(_movie.frame + 1);
    }
}

See also
BACKSPACE, EMPTY, RETURN (constant)
**TRUE**

**Usage**

```-- Lingo syntax
TRUE
```

```// JavaScript syntax
true
```

**Description**

Constant; represents the value of a logically true expression, such as $2 < 3$. It has a traditional numerical value of 1, but any nonzero integer evaluates to `TRUE` in a comparison.

**Example**

This statement turns on the `_sound.soundEnabled` property by setting it to `TRUE`:

```-- Lingo syntax
_sound.soundEnabled = TRUE
```

```// JavaScript syntax
_sound.soundEnabled = true;
```

**See also**

`FALSE`, `if`

---

**VOID**

**Usage**

```-- Lingo syntax
VOID
```

```// JavaScript syntax
null
```

**Description**

Constant; indicates the value `VOID`.

**Example**

This statement checks whether the value in the variable `currentVariable` is `VOID`:

```-- Lingo syntax
if currentVariable = VOID then
    put("This variable has no value")
end if
```

```// JavaScript syntax
if (currentVariable == null) {
    put("This variable has no value");
}
```

**See also**

`voidP()`
This section provides an alphabetical list of all the events and messages available in Macromedia Director MX 2004.

on activateApplication

Usage

-- Lingo syntax
on activateApplication
    statement(s)
end

// JavaScript syntax
function activateApplication() {
    statement(s);
}

Description

Built-in handler; runs when the projector is brought to the foreground. This handler is useful when a projector runs in a window and the user can send it to the background to work with other applications. When the projector is brought back to the foreground, this handler runs. Any MIAWs running in the projector can also make use of this handler.

During authoring, this handler is called only if Animate in Background is turned on in General Preferences.

On Windows, this handler is not called if the projector is merely minimized and no other application is brought to the foreground.
Example

This handler plays a sound each time the user brings the projector back to the foreground:

```-- Lingo syntax
on activateApplication
    sound(1).queue(member("openSound"))
    sound(1).play()
end

// JavaScript syntax
function activateApplication() {
    sound(1).queue(member("openSound"));
    sound(1).play();
}
```

See also

on deactivateApplication, activeCastLib, on deactivateWindow

on activateWindow

Usage

```-- Lingo syntax
on activateWindow
    statement(s)
end

// JavaScript syntax
function activateWindow()
    statement(s);
```

Description

System message and event handler; contains statements that run in a movie when the user clicks the inactive window and the window comes to the foreground.

You can use an on activateWindow handler in a script that you want executed every time the movie becomes active.

Clicking the main movie (the main Stage) does not generate an on activateWindow handler.

Example

This handler plays the sound Hurray when the window that the movie is playing in becomes active:

```-- Lingo syntax
on activateWindow
    sound(2).play(member("Hurray"))
end

// JavaScript syntax
function activateWindow() {
    sound(2).play(member("Hurray"));
}
on beginSprite

Usage

-- Lingo syntax
on beginSprite
  statement(s)
end

// JavaScript syntax
function beginSprite() {
  statement(s);
}

Description

System message and event handler; contains statements that run when the playhead moves to a frame that contains a sprite that was not previously encountered. Like endSprite, this event is generated only one time, even if the playhead loops on a frame, since the trigger is a sprite not previously encountered by the playhead. The event is generated before prepareFrame.

Director creates instances of any behavior scripts attached to the sprite when the beginSprite message is sent.

The object reference me is passed to this event if it is used in a behavior. The message is sent to behaviors and frame scripts.

If a sprite begins in the first frame that plays in the movie, the beginSprite message is sent after the prepareMovie message but before the prepareFrame and startMovie messages.

Note: Be aware that some sprite properties, such as the rect sprite property, may not be accessible in a beginSprite handler. This is because the property needs to be calculated, which is not done until the sprite is drawn.

The go, play, and updateStage commands are disabled in an on beginSprite handler.

Example

This handler plays the sound cast member Stevie Wonder when the sprite begins:

-- Lingo syntax
on beginSprite me
  sound(1).play(member("Stevie Wonder"))
end

// JavaScript syntax
function beginSprite() {
  sound(1).play(member("Stevie Wonder"));
}

See also

on endSprite, on prepareFrame, scriptInstanceList
on closeWindow

Usage
-- Lingo syntax
on closeWindow
  statement(s)
end

// JavaScript syntax
function closeWindow() {
  statement(s);
}

Description
System message and event handler; contains statements that run when the user closes the window for a movie by clicking the window's close box.

The on closeWindow handler is a good place to put Lingo commands that you want executed every time the movie's window closes.

Example
This handler tells Director to forget the current window when the user closes the window that the movie is playing in:

-- Lingo syntax
on closeWindow
  -- perform general housekeeping here
  window(1).forget()
end

// JavaScript syntax
function closeWindow() {
  // perform general housekeeping here
  window(1).forget();
}

on cuePassed

Usage
-- Lingo syntax
on cuePassed({me,} channelId, cuePointNumber, cuePointName)
  statement(s)
end

// JavaScript syntax
function cuePassed(channelId, cuePointNumber, cuePointName) {
  statement(s);
}

Description
System message and event handler; contains statements that run each time a sound or sprite passes a cue point in its media.

- me
  The optional me parameter is the scriptInstanceRef value of the script being invoked. You must include this parameter when using the message in a behavior. If this parameter is omitted, the other arguments will not be processed correctly.
• **channelID**  The number of the sound or sprite channel for the file where the cue point occurred.
• **cuePointNumber**  The ordinal number of the cue point that triggers the event in the list of the cast member's cue points.
• **cuePointName**  The name of the cue point that was encountered.

The message is passed—in order—to sprite, cast member, frame, and movie scripts. For the sprite to receive the event, it must be the source of the sound, like a QuickTime movie or SWA cast member. Use the `isPastCuePoint` property to check cues in behaviors on sprites that don't generate sounds.

**Example**

This handler placed in a Movie or Frame script reports any cue points in sound channel 1 to the Message window:

```lingo
-- Lingo syntax
on cuePassed channel, number, name
    if (channel = #Sound1) then
        put("CuePoint" && number && "named" && name && "occurred in sound 1")
    end if
end
```

```javascript
function cuePassed(channel, number, name) {
    if (channel == symbol("Sound1")) {
        put("CuePoint " + number + " named " + name + " occurred in sound 1");
    }
}
```

**See also**

`scriptInstanceList`, `cuePointNames`, `cuePointTimes`, `isPastCuePoint()`

---

**on deactivateApplication**

**Usage**

```lingo
-- Lingo syntax
on deactivateApplication
    statement(s)
end
```

```javascript
function deactivateApplication() {
    statement(s);
}
```

**Description**

Built-in handler; runs when the projector is sent to the background. This handler is useful when a projector runs in a window and the user can send it to the background to work with other applications. Any MIAWs running in the projector can also make use of this handler.

During authoring, this handler is called only if Animate in Background is turned on in General Preferences.

On Windows, this handler is not called if the projector is merely minimized and no other application is brought to the foreground.
Example

This handler plays a sound each time the user sends the projector to the background:

```lingo
-- Lingo syntax
on deactivateApplication
    sound(1).queue(member("closeSound"))
    sound(1).play()
end

// JavaScript syntax
function deactivateApplication() {
    sound(1).queue(member("closeSound"));
    sound(1).play();
}
```

See also

`add (3D texture), activeCastLib, on deactivateWindow`

### on deactivateWindow

#### Usage

```lingo
-- Lingo syntax
on deactivateWindow
    statement(s)
end

// JavaScript syntax
function deactivateWindow() {
    statement(s);
}
```

#### Description

System message and event handler; contains statements that run when the window that the movie is playing in is deactivated. The `on deactivate` event handler is a good place for Lingo that you want executed whenever a window is deactivated.

#### Example

This handler plays the sound Snore when the window that the movie is playing in is deactivated:

```lingo
-- Lingo syntax
on deactivateWindow
    sound(2).play(member("Snore"))
end

// JavaScript syntax
function deactivateWindow() {
    sound(2).play(member("Snore"));
}
```
on DVDeventNotification

Usage

-- Lingo syntax
on DVDeventNotification eventArg1 {, eventArg2} {, eventArg3}
    statement(s)
end DVDeventNotification

// JavaScript syntax
function DVDeventNotification(eventArg1 {, eventArg2} {, eventArg3}) {
    statement(s);
}

Description

Built-in DVD event handler. Contains statements that run in response to events that occur while a DVD is playing.

This handler is used to handle all DVD events. The actual event that occurs is always passed as the first parameter, `eventArg1`. Some events contain additional information about them that is passed as a second parameter, `eventArg2`, and in some cases a third parameter, `eventArg3`.

The following table lists the events that can occur while a DVD is playing.

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>angleChange</td>
<td>Occurs when either the number of available angles changed or the current user angle number changed. The following additional information is passed to <code>DVDeventNotification</code> when this event occurs:</td>
</tr>
<tr>
<td></td>
<td>• <code>eventArg2</code> - An integer or address that indicates the number of available angles. When the number of available angles is 1, the current video is not multiangle.</td>
</tr>
<tr>
<td></td>
<td>• <code>eventArg3</code> - An integer or address that indicates the current user angle number.</td>
</tr>
<tr>
<td>audioStreamChange</td>
<td>Occurs when the current user audio stream number changed for the main title. The following additional information is passed to <code>DVDeventNotification</code> when this event occurs:</td>
</tr>
<tr>
<td></td>
<td>• <code>eventArg2</code> - An integer or address that indicates the new user audio stream number. Stream <code>0xFFFFFFFF</code> indicates that no stream is selected.</td>
</tr>
<tr>
<td>buttonChange</td>
<td>Occurs when either the number of available buttons changed or the currently selected button number changed. The following additional information is passed to <code>DVDeventNotification</code> when this event occurs:</td>
</tr>
<tr>
<td></td>
<td>• <code>eventArg2</code> - An integer or address that indicates the number of available buttons.</td>
</tr>
<tr>
<td></td>
<td>• <code>eventArg3</code> - An integer or address that indicates the currently selected button number. Selected button number 0 implies that no button is selected.</td>
</tr>
<tr>
<td>chapterAutoStop</td>
<td>Occurs when playback stopped as a result of a call to <code>chapterPlayAutoStop()</code>.</td>
</tr>
<tr>
<td>Event</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>chapterStart</td>
<td>Occurs when playback of a new program in the title domain starts. The following additional information is passed to DVDeventNotification when this event occurs:</td>
</tr>
<tr>
<td></td>
<td>• eventArg2: An integer or address that indicates the new chapter number.</td>
</tr>
<tr>
<td>diskEjected</td>
<td>Occurs when a DVD is ejected.</td>
</tr>
<tr>
<td>diskInserted</td>
<td>Occurs when a DVD is inserted.</td>
</tr>
<tr>
<td>domainChange</td>
<td>Occurs when the DVD player’s domain changes. The following additional information is passed to DVDeventNotification when this event occurs:</td>
</tr>
<tr>
<td></td>
<td>• eventArg2: A value that indicates the new domain. The new domain will be one of the following values.</td>
</tr>
<tr>
<td></td>
<td>• firstPlay: The DVD Navigator is performing default initialization of a DVD.</td>
</tr>
<tr>
<td></td>
<td>• videoManagerMenu: The DVD Navigator is displaying menus for the whole disc.</td>
</tr>
<tr>
<td></td>
<td>• videoTitleSetMenu: The DVD Navigator is displaying menus for the current title set.</td>
</tr>
<tr>
<td></td>
<td>• title: The DVD Navigator is displaying the current title.</td>
</tr>
<tr>
<td></td>
<td>• stop: The DVD Navigator is in the stop domain.</td>
</tr>
<tr>
<td>error</td>
<td>Occurs when a DVD error condition is encountered. The following additional information is passed to DVDeventNotification when this event occurs:</td>
</tr>
<tr>
<td></td>
<td>• eventArg2: A value that indicates error condition. The error condition will be one of the following values.</td>
</tr>
<tr>
<td></td>
<td>• copyProtectFail: Key exchange for DVD copy protection failed. Playback is stopped.</td>
</tr>
<tr>
<td></td>
<td>• invalidDVD1_0Disc: DVD-Video disc is authored incorrectly for specification version 1.x. Playback is stopped.</td>
</tr>
<tr>
<td></td>
<td>• invalidDiscRegion: DVD-Video disc cannot be played because the disc is not authored to play in the system region.</td>
</tr>
<tr>
<td></td>
<td>• lowParentalLevel: Player parental level is lower than the lowest parental level available in the DVD content. Playback is stopped.</td>
</tr>
<tr>
<td></td>
<td>• macrovisionFail: Macrovision distribution failed. Playback stopped.</td>
</tr>
<tr>
<td></td>
<td>• incompatibleSystemAndDecoderRegions: No discs can be played because the system region does not match the decoder region.</td>
</tr>
<tr>
<td></td>
<td>• incompatibleDiscAndDecoderRegions: The disc cannot be played because the disc is not authored to be played in the decoder’s region.</td>
</tr>
<tr>
<td></td>
<td>• unexpected: Something unexpected happened; perhaps content is authored incorrectly. Playback is stopped.</td>
</tr>
<tr>
<td>karaokeMode</td>
<td>Occurs when the audio mode is set to karaoke.</td>
</tr>
<tr>
<td>noFirstPlayChain</td>
<td>Occurs when the DVD disc does not have a FP_PGC (First Play Program Chain) and that the DVD Navigator will not automatically load any PGC and start playback.</td>
</tr>
<tr>
<td>Event</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| parentalLevelChange | Occurs when the parental level of the authored content is about to change. The following additional information is passed to DVDeventNotification when this event occurs:  
  • `eventArg2` - An integer that indicates the new parental level set in the player. |
| playbackStopped     | Occurs when playback stops. The DVD Navigator has completed playback of the PGC and did not find any other branching instruction for subsequent playback. |
| playPeriodAutoStop  | Occurs when the playback rate changes. The following additional information is passed to DVDeventNotification when this event occurs:  
  • `eventArg2` - An integer that indicates the new playback rate. A value that is less than (>) 0 indicates reverse playback mode. A value that is greater than (<) 0 indicates forward playback mode. This value is the actual playback rate multiplied by 10,000. |
| stillOff            | Occurs at the end of any still (PGC, Cell, or VOBU).                                                                                           |
| stillOn             | Occurs at the beginning of any still (PGC, Cell, or VOBU). The following additional information is passed to DVDeventNotification when this event occurs:  
  • `eventArg2` - A boolean that indicates whether buttons are available. Zero (0) indicates buttons are available. One (1) indicates no buttons are available.  
  • `eventArg3` - An integer or address that indicates the number of seconds the still will last. `0xFFFFFFFF` indicates an infinite still. |
| titleChange         | Occurs when the current title number changes. The following additional information is passed to DVDeventNotification when this event occurs:  
  • `eventArg2` - An integer or address that indicates the new title number. |
on endSprite

Usage

-- Lingo syntax
on endSprite
    statement(s)
end

// JavaScript syntax
function endSprite() {
    statement(s);
}

Description

System message and event handler; contains Lingo that runs when the playhead leaves a sprite and goes to a frame in which the sprite doesn't exist. It is generated after exitFrame.

Place on endSprite handlers in a behavior script.

Director destroys instances of any behavior scripts attached to the sprite immediately after the endSprite event occurs.

The event handler is passed the behavior or frame script reference me if used in a behavior. This endSprite message is sent after the exitFrame message if the playhead plays to the end of the frame.

The go(), play(), and updateStage() methods are disabled in an on endSprite handler.
Example

This handler runs when the playhead exits a sprite:

```
-- Lingo syntax
on endSprite me
   -- clean up
   gNumberOfSharks = gNumberOfSharks - 1
   sound(5).stop()
end

// JavaScript syntax
function endSprite() {
   // clean up
   gNumberOfSharks--;
   sound(5).stop();
}
```

See also

- `on beginSprite`
- `on exitFrame`

on enterFrame

Usage

```
-- Lingo syntax
on enterFrame
   statement(s)
end

// JavaScript syntax
function enterFrame() {
   statement(s);
}
```

Description

System message and event handler; contains statements that run each time the playhead enters the frame.

Place `on enterFrame` handlers in behavior, frame, or movie scripts, as follows:

- To assign the handler to an individual sprite, put the handler in a behavior attached to the sprite.
- To assign the handler to an individual frame, put the handler in the frame script.
- To assign the handler to every frame (unless you explicitly instruct the movie otherwise), put the `on enterFrame` handler in a movie script. The handler executes every time the playhead enters a frame unless the frame script has its own handler. If the frame script has its own handler, the `on enterFrame handler in the frame script overrides the on enterFrame handler in the movie script.

The order of frame events is `stepFrame, prepareFrame, enterFrame, and exitFrame`.

This event is passed the object reference `me` if used in a behavior.
Example

This handler turns off the puppet condition for sprites 1 through 5 each time the playhead enters the frame:

```
-- Lingo syntax
on enterFrame
  repeat with i = 1 to 5
    _movie.puppetSprite(i, FALSE)
  end repeat
end

// JavaScript syntax
function enterFrame() {
  for (i=1;i<=5;i++) {
    _movie.puppetSprite(i, false);
  }
}
```

on EvalScript

Usage

```
-- Lingo syntax
on EvalScript aParam
  statement(s)
end

// JavaScript syntax
function EvalScript(aParam) {
  statement(s);
}
```

Description

System message and event handler; in a movie with Macromedia Shockwave content, contains statements that run when the handler receives an `EvalScript` message from a browser. The parameter is a string passed in from the browser.

- The `EvalScript` message can include a string that Director can interpret as a Lingo statement. Lingo cannot accept nested strings. If the handler you are calling expects a string as a parameter, pass the parameter as a symbol.
- The `on EvalScript` handler is called by the `EvalScript()` scripting method from JavaScript or VBScript in a browser.

Include only those behaviors in `on EvalScript` that you want users to control; for security reasons, don’t give complete access to behaviors.

Note: If you place a return at the end of your `EvalScript` handler, the value returned can be used by JavaScript in the browser.
Example

This shows how to make the playhead jump to a specific frame depending on what frame is passed in as the parameter:

-- Lingo syntax
on EvalScript aParam
_movie.go(aParam)
end

// JavaScript syntax
function EvalScript(aParam) {
_movie.go(aParam);
}

This handler runs the statement _movie.go(aParam) if it receives an EvalScript message that includes dog, cat, or tree as an argument:

-- Lingo syntax
on EvalScript aParam
  case aParam of
    "dog", "cat", "tree": _movie.go(aParam)
  end case
end

// JavaScript syntax
function EvalScript(aParam) {
  switch(aParam) {
    case "dog", "cat", "tree": _movie.go(aParam);
  }
}

A possible calling statement for this in JavaScript would be EvalScript("dog").

This handler takes an argument that can be a number or symbol:

-- Lingo syntax
on EvalScript aParam
  if word 1 of aParam = "myHandler" then
    _movie.go(aParam)
  end if
end

// JavaScript syntax
function EvalScript(aParam) {
  if (aParam.indexOf("myHandler",0)) {
    _movie.go(aParam);
  }
}

The following handler normally requires a string as its argument. The argument is received as a symbol and then converted to a string within the handler by the string function:

-- Lingo syntax
on myHandler aParam
_movie.go(string(aParam))
end

// JavaScript syntax
function myHandler(aParam) {
_movie.go(aParam.toString());
}

See also

externalEvent(), return (keyword)
on exitFrame

Usage

-- Lingo syntax
on exitFrame
    statement(s)
end

// JavaScript syntax
function exitFrame() {
    statement(s);
}

Description

System message and event handler; contains statements that run each time the playhead exits the frame that the on exitFrame handler is attached to. The on exitFrame handler is a useful place for Lingo that resets conditions that are no longer appropriate after leaving the frame.

Place on exitFrame handlers in behavior, frame, or movie scripts, as follows:

- To assign the handler to an individual sprite, put the handler in a behavior attached to the sprite.
- To assign the handler to an individual frame, put the handler in the frame script.
- To assign the handler to every frame unless explicitly instructed otherwise, put the handler in a movie script. The on exitFrame handler then executes every time the playhead exits the frame unless the frame script has its own on exitFrame handler. When the frame script has its own on exitFrame handler, the on exitFrame handler in the frame script overrides the one in the movie script.

This event is passed the sprite script or frame script reference me if it is used in a behavior. The order of frame events is prepareFrame, enterFrame, and exitFrame.

Example

This handler turns off all puppet conditions when the playhead exits the frame:

-- Lingo syntax
on exitFrame me
    repeat with i = 48 down to 1
        sprite(i).scripted = FALSE
    end repeat
end

// JavaScript syntax
function exitFrame() {
    for (i=48; i>=1; i--);
        sprite(i).scripted = false;
    }
}
This handler branches the playhead to a specified frame if the value in the global variable _vTotal exceeds 1000 when the playhead exits the frame:

```javascript
// JavaScript syntax
function exitFrame() {  
  if (_global._vTotal > 1000) {  
    _movie.go("Finished");  
  }  
}
```

*on enterFrame*

### on getBehaviorDescription

**Usage**

---

**Lingo syntax**

```lingo
on getBehaviorDescription
  statement(s)
end
```

---

**JavaScript syntax**

```javascript
function getBehaviorDescription() {
  statement(s);
}
```

**Description**

System message and event handler: contains Lingo that returns the string that appears in a behavior’s description pane in the Behavior Inspector when the behavior is selected.

The description string is optional.

Director sends the `getBehaviorDescription` message to the behaviors attached to a sprite when the Behavior inspector opens. Place the `on getBehaviorDescription` handler within a behavior.

The handler can contain embedded Return characters for formatting multiple-line descriptions.

**Example**

This statement displays “Vertical Multiline textField Scrollbar” in the description pane:

---

**Lingo syntax**

```lingo
on getBehaviorDescription
  return "Vertical Multiline textField Scrollbar"
end
```

---

**JavaScript syntax**

```javascript
function getBehaviorDescription() {
  return "Vertical Multiline textField Scrollbar";
}
```

See also

* on getPropertyDescriptionList, on getBehaviorTooltip, on runPropertyDialog*
on getBehaviorTooltip

Usage
-- Lingo syntax
on getBehaviorTooltip
statement(s)
end

// JavaScript syntax
function getBehaviorTooltip() {
    statement(s);
}

Description
System message and event handler; contains Lingo that returns the string that appears in a tooltip for a script in the Library palette.

Director sends the getBehaviorTooltip message to the script when the cursor stops over it in the Library palette. Place the on getBehaviorTooltip handler within the behavior.

The use of the handler is optional. If no handler is supplied, the cast member name appears in the tooltip.

The handler can contain embedded Return characters for formatting multiple-line descriptions.

Example
This statement displays “Jigsaw puzzle piece” in the description pane:

-- Lingo syntax
on getBehaviorTooltip
    return "Jigsaw puzzle piece"
end

// JavaScript syntax
function getBehaviorTooltip() {
    return "Jigsaw puzzle piece";
}

See also
on getPropertyDescriptionList, on getBehaviorDescription, on runPropertyDialog

on getPropertyDescriptionList

Usage
-- Lingo syntax
on getPropertyDescriptionList
    statement(s)
end

// JavaScript syntax
function getPropertyDescriptionList() {
    statement(s);
}
Description

System message and event handler; contains Lingo that generates a list of definitions and labels for the parameters that appear in a behavior's Parameters dialog box.

Place the on getPropertyDescriptionList handler within a behavior script. Behaviors that don't contain an on getPropertyDescriptionList handler don't appear in the Parameters dialog box and can't be edited from the Director interface.

The on getPropertyDescriptionList message is sent when any action that causes the Behavior Inspector to open occurs: either when the user drags a behavior to the Score or the user double-clicks a behavior in the Behavior inspector.

The #default, #format, and #comment settings are mandatory for each parameter. The following are possible values for these settings:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#default</td>
<td>The parameter's initial setting.</td>
</tr>
<tr>
<td>#format</td>
<td>integer</td>
</tr>
<tr>
<td>#comment</td>
<td>A descriptive string that appears to the left of the parameter's editable field in the Parameters dialog box.</td>
</tr>
<tr>
<td>#range</td>
<td>A range of possible values that can be assigned to a property. The range is specified as a linear list with several values or as a minimum and maximum in the form of a property list: [min: minValue, max: maxValue].</td>
</tr>
</tbody>
</table>

Example

The following handler defines a behavior's parameters that appear in the Parameters dialog box. Each statement that begins with addProp adds a parameter to the list named description. Each element added to the list defines a property and the property's #default, #format, and #comment values:

```lingo
on getPropertyDescriptionList
description = [
    description.addProp(#dynamic, [#default:1, #format:#boolean, 
        #comment:"Dynamic"])
    description.addProp(#fieldNum, [#default:1, #format:#integer, 
        #comment:"Scroll which sprite:"])
    description.addProp(#extentSprite, [#default:1,#format:#integer, 
        #comment:"Extend Sprite:"])
    description.addProp(#proportional, [#default:1,#format:#boolean, 
        #comment:"Proportional:"])
]
return description
end
```

See also

addProp, on getBehaviorDescription, on runPropertyDialog
on hyperlinkClicked

Usage
-- Lingo syntax
on hyperlinkClicked me, data, range
  statement(s)
end

// JavaScript syntax
function hyperlinkClicked(data, range) {
  statement(s);
}

Description
System message and event handler; used to determine when a hyperlink is actually clicked.

This event handler has the following parameters:

• me Used in a behavior to identify the sprite instance
• data The hyperlink data itself; the string entered in the Text inspector when editing the text cast member
• range The character range of the hyperlink in the text (It’s possible to get the text of the range itself by using the syntax member Ref.char[range[1]..range[2]])

This handler should be attached to a sprite as a behavior script. Avoid placing this handler in a cast member script.

Example
This behavior shows a link examining the hyperlink that was clicked, jump to a URL if needed, then output the text of the link itself to the message window:

-- Lingo syntax
property spriteNum

on hyperlinkClicked(me, data, range)
  if data starts "http://" then
    gotoNetPage(data)
  end if
  currentMember = sprite(spriteNum).member
  anchorString = currentMember.char[range[1]..range[2]]
  put("The hyperlink on "& anchorString & " was just clicked.")
end

// JavaScript syntax
function hyperlinkClicked(data, range) {
  var st = data.slice(0, 7);
  var ht = "http://";
  if (st = ht) {
    gotoNetPage(data);
  }
  var currentMember = sprite(this.spriteNum).member;
  var r1 = currentMember.getPropRef("char", range[1]).hyperlinkRange;
  var a = r1[1] - 1;
  var b = r1[2];
  var st = new String(currentMember.text);
  var anchorString = st.slice(a, b);
  put("The hyperlink on " + anchorString + " was just clicked.");
}
on idle

Usage

-- Lingo syntax
on idle
  statement(s)
end

// JavaScript syntax
function idle() {
  statement(s);
}

Description

System message and event handler; contains statements that run whenever the movie has no other
events to handle and is a useful location for Lingo statements that you want to execute as
frequently as possible, such as statements that update values in global variables and displays
current movie conditions.

Because statements in on idle handlers run frequently, it is good practice to avoid placing Lingo
that takes a long time to process in an on idle handler.

It is often preferable to put on idle handlers in frame scripts instead of movie scripts to take
advantage of the on idle handler only when appropriate.

Director can load cast members from an internal or external cast during an idle event. However,
it cannot load linked cast members during an idle event.

The idle message is only sent to frame scripts and movie scripts.

Example

This handler updates the time being displayed in the movie whenever there are no other events to
handle:

-- Lingo syntax
on idle
  member("Time").text = _system.time()
end idle

// JavaScript syntax
function idle() {
  member("Time").text = _system.time();
}

See also

idleHandlerPeriod
on isOKToAttach

Usage

-- Lingo syntax
on isOKToAttach me, aSpriteType, aSpriteNum
  statement(s)
end

// JavaScript syntax
function isOKToAttach(aSpriteType, aSpriteNum) {
  statement(s)
}

Description

Built-in handler; you can add this handler to a behavior in order to check the type of sprite the
behavior is being attached to and prevent the behavior from being attached to inappropriate
sprite types.

When the behavior is attached to a sprite, the handler executes and Director passes to it the type
of the sprite and its sprite number. The me argument contains a reference to the behavior that is
being attached to the sprite.

This handler runs before the on getPropertyDescriptionList handler.

The Lingo author can check for two types of sprites. #graphic includes all graphic cast members,
such as shapes, bitmaps, digital video, text, and so on. #script indicates the behavior was
attached to the script channel. In this case, the spriteNum is 1.

For each of these sprite types, the handler must return TRUE or FALSE. A value of TRUE indicates
that the behavior can be attached to the sprite. A value of FALSE prevents the behavior from being
attached to the sprite.

If the behavior contains no on isOKToAttach handler, then the behavior can be attached to any
sprite or frame.

This handler is called during the initial attachment of the behavior to the sprite or script channel
and also when attaching a new behavior to a sprite using the Behavior inspector.

Example

This statement checks the sprite type the behavior is being attached to and returns TRUE for any
graphic sprite except a shape and FALSE for the script channel:

-- Lingo syntax
on isOKToAttach me, aSpriteType, aSpriteNum
  case aSpriteType of
    #graphic: -- any graphic sprite type
      return sprite(aSpriteNum).member.type <> #shape
        -- works for everything but shape cast members
    #script: --the frame script channel
      return FALSE -- doesn't work as a frame script
  end case
end
// JavaScript syntax
function isOKToAttach(aSpriteType, aSpriteNum) {
  switch (aSpriteType) {
    case symbol("graphic"): // any graphic sprite type
      return sprite(aSpriteNum).member.type != symbol("shape");
    // works for everything but shape cast members
    case symbol("script"): // the frame script channel
      return false; // doesn't work as a frame script
  }
}

on keyDown

Usage
--- Lingo syntax
on keyDown
  statement(s)
end

// JavaScript syntax
function keyDown() {
  statement(s);
}

Description
System message and event handler; contains statements that run when a key is pressed.

When a key is pressed, Director searches these locations, in order, for an on keyDown handler:
primary event handler, editable field sprite script, field cast member script, frame script, and
movie script. For sprites and cast members, on keyDown handlers work only for editable text and
field members. A keyDown event on a different type of cast member, such as a bitmap, has no
effect. (If pressing a key should have the same response throughout the movie, set
keyDownScript.)

Director stops searching when it reaches the first location that has an on keyDown handler,
unless the handler includes the pass command to explicitly pass the keyDown message on to the
next location.

The on keyDown event handler is a good place to put Lingo that implements keyboard shortcuts
or other interface features that you want to occur when the user presses keys.

When the movie plays back as an applet, an on keyDown handler always traps key presses, even if
the handler is empty. If the user is typing in an editable field, an on keyDown handler attached to
the field must include the pass command for the key to appear in the field.

Where you place an on keyDown handler can affect when it runs.
• To apply the handler to a specific editable field sprite, put the handler in a sprite script.
• To apply the handler to an editable field cast member in general, put the handler in a cast
  member script.
• To apply the handler to an entire frame, put the handler in a frame script.
• To apply the handler throughout the entire movie, put the handler in a movie script.
You can override an `on keyDown` handler by placing an alternative `on keyDown` handler in a location that Lingo checks before it gets to the handler you want to override. For example, you can override an `on keyDown` handler assigned to a cast member by placing an `on keyDown` handler in a sprite script.

**Example**

This handler checks whether the Return key was pressed and if it was, sends the playhead to another frame:

```-- Lingo syntax
on keyDown
  if (_key.key = RETURN) then _movie.go("AddSum")
end keyDown

// JavaScript syntax
function keyDown() {
  if (_key.keyCode == 36) {
    _movie.go("AddSum");
  }
}
```

**See also**

`charToNum()`, `keyDownScript`, `keyUpScript`, `key`, `keyCode`, `keyPressed()`

---

**on keyUp**

**Usage**

```-- Lingo syntax
on keyUp
  statement(s)
end

// JavaScript syntax
function keyUp() {
  statement(s);
}
```

**Description**

System message and event handler; contains statements that run when a key is released. The `on keyUp` handler is similar to the `on keyDown` handler, except this event occurs after a character appears if a field or text sprite is editable on the screen.

When a key is released, Lingo searches these locations, in order, for an `on keyUp` handler: primary event handler, editable field sprite script, field cast member script, frame script, and movie script. For sprites and cast members, `on keyUp` handlers work only for editable strings. A `keyUp` event on a different type of cast member, such as a bitmap, has no effect. If releasing a key should always have the same response throughout the movie, set `keyUpScript`.

Lingo stops searching when it reaches the first location that has an `on keyUp` handler, unless the handler includes the `pass` command to explicitly pass the `keyUp` message on to the next location.

The `on keyUp` event handler is a good place to put Lingo that implements keyboard shortcuts or other interface features that you want to occur when the user releases keys.
When the movie plays back as an applet, an on keyUp handler always traps key presses, even if the handler is empty. If the user is typing in an editable field, an on keyUp handler attached to the field must include the pass command for the key to appear in the field.

Where you place an on keyUp handler can affect when it runs, as follows:

- To apply the handler to a specific editable field sprite, put it in a behavior.
- To apply the handler to an editable field cast member in general, put it in a cast member script.
- To apply the handler to an entire frame, put it in a frame script.
- To apply the handler throughout the entire movie, put it in a movie script.

You can override an on keyUp handler by placing an alternative on keyUp handler in a location that Lingo checks before it gets to the handler you want to override. For example, you can override an on keyUp handler assigned to a cast member by placing an on keyUp handler in a sprite script.

Example

This handler checks whether the Return key was released and if it was, sends the playhead to another frame:

-- Lingo syntax
on keyUp
  if (_key.key = RETURN) then _movie.go("AddSum")
end keyUp

// JavaScript syntax
function keyUp() {
  if (_key.keyCode == 36) {
    _movie.go("AddSum");
  }
}

See also

on keyDown, keyDownScript, keyUpScript

on mouseDown (event handler)

Usage

-- Lingo syntax
on mouseDown
  statement(s)
end

// JavaScript syntax
function mouseDown() {
  statement(s);
}

Description

System message and event handler; contains statements that run when the mouse button is pressed.
When the mouse button is pressed, Lingo searches the following locations, in order, for an `on mouseDown` handler: primary event handler, sprite script, cast member script, frame script, and movie script. Lingo stops searching when it reaches the first location that has an `on mouseDown` handler, unless the handler includes the `pass` command to explicitly pass the `mouseDown` message on to the next location.

To have the same response throughout the movie when pressing the mouse button, set `mouseDownScript` or put a `mouseDown` handler in a Movie script.

The `on mouseDown` event handler is a good place to put Lingo that flashes images, triggers sound effects, or makes sprites move when the user presses the mouse button.

Where you place an `on mouseDown` handler can affect when it runs.

- To apply the handler to a specific sprite, put it in a sprite script.
- To apply the handler to a cast member in general, put it in a cast member script.
- To apply the handler to an entire frame, put it in a frame script.
- To apply the handler throughout the entire movie, put it in a movie script.

You can override an `on mouseDown` handler by placing an alternative `on mouseDown` handler in a location that Lingo checks before it gets to the handler you want to override. For example, you can override an `on mouseDown` handler assigned to a cast member by placing an `on mouseDown` handler in a sprite script.

If used in a behavior, this event is passed the sprite script or frame script reference `me`.

Example

This handler checks whether the user clicks anywhere on the Stage and sends the playhead to another frame if a click occurs:

```-- Lingo syntax
on mouseDown
if (_mouse.clickOn = 0) then _movie.go("AddSum")
end
```

```// JavaScript syntax
function mouseDown() {
    if (_mouse.clickOn == 0) {
        _movie.go("AddSum");
    }
}
```

This handler, assigned to a sprite script, plays a sound when the sprite is clicked:

```-- Lingo syntax
on mouseDown
    sound(1).play(member("Crickets"))
end
```

```// JavaScript syntax
function mouseDown() {
    sound(1).play(member("Crickets"));
}
```

See also

`clickOn`, `mouseDownScript`, `mouseUpScript`
**on mouseEnter**

**Usage**

```
-- Lingo syntax
on mouseEnter
  statement(s)
end

// JavaScript syntax
function mouseEnter() {
  statement(s);
}
```

**Description**

System message and event handler; contains statements that run when the mouse pointer first contacts the active area of the sprite. The mouse button does not have to be pressed.

If the sprite is a bitmap cast member with matte ink applied, the active area is the portion of the image that is displayed; otherwise, the active area is the sprite's bounding rectangle.

If used in a behavior, this event is passed the sprite script or frame script reference `me`.

**Example**

This example is a simple button behavior that switches the bitmap of the button when the mouse rolls over and then off the button:

```
-- Lingo syntax
property spriteNum

on mouseEnter me
  -- Determine current cast member and switch to next in cast
  currentMember = sprite(spriteNum).member.number
  sprite(spriteNum).member = currentMember + 1
end

on mouseLeave me
  -- Determine current cast member and switch to previous in cast
  currentMember = sprite(spriteNum).member.number
  sprite(spriteNum).member = currentMember - 1
end

// JavaScript syntax
var spriteNum;

function mouseEnter() {
  // Determine current cast member and switch to next in cast
  currentMember = sprite(spriteNum).member.number;
  sprite(spriteNum).member = currentMember + 1;
}

function mouseLeave() {
  // Determine current cast member and switch to previous in cast
  currentMember = sprite(spriteNum).member.number;
  sprite(spriteNum).member = currentMember - 1;
}
```

**See also**

- `on mouseLeave`
- `on mouseWithin`
**on mouseLeave**

**Usage**

-- Lingo syntax
on mouseLeave
  statement(s)
end

// JavaScript syntax
function mouseLeave() {
  statement(s);
}

**Description**

System message and event handler; contains statements that run when the mouse leaves the active area of the sprite. The mouse button does not have to be pressed.

If the sprite is a bitmap cast member with the matte ink applied, the active area is the portion of the image that is displayed; otherwise, the active area is the sprite’s bounding rectangle.

If used in a behavior, this event is passed the sprite script or frame script reference `me`.

**Example**

This statement shows a simple button behavior that switches the bitmap of the button when the mouse pointer rolls over and then back off the button:

-- Lingo syntax
property spriteNum

on mouseEnter me
  -- Determine current cast member and switch to next in cast
  currentMember = sprite(spriteNum).member.number
  sprite(spriteNum).member = currentMember + 1
end

on mouseLeave me
  -- Determine current cast member and switch to previous in cast
  currentMember = sprite(spriteNum).member.number
  sprite(spriteNum).member = currentMember - 1
end

// JavaScript syntax
var spriteNum;

function mouseEnter() {
  // Determine current cast member and switch to next in cast
  currentMember = sprite(spriteNum).member.number;
  sprite(spriteNum).member = currentMember + 1;
}

function mouseLeave() {
  // Determine current cast member and switch to previous in cast
  currentMember = sprite(spriteNum).member.number;
  sprite(spriteNum).member = currentMember - 1;
}

**See also**

on mouseEnter, on mouseWithin
on mouseUp (event handler)

Usage

-- Lingo syntax
on mouseUp
  statement(s)
end

// JavaScript syntax
function mouseUp() {
  statement(s);
}

Description

System message and event handler; contains statements that are activated when the mouse button is released.

When the mouse button is released, Lingo searches the following locations, in order, for an on mouseUp handler: primary event handler, sprite script, cast member script, frame script, and movie script. Lingo stops searching when it reaches the first location that has an on mouseUp handler, unless the handler includes the pass command to explicitly pass the mouseUp message on to the next location.

To create the same response throughout the movie when the user releases the mouse button, set the mouseUpScript.

An on mouseUp event handler is a good place to put Lingo that changes the appearance of objects—such as buttons—after they are clicked. You can do this by switching the cast member assigned to the sprite after the sprite is clicked and the mouse button is released.

Where you place an on mouseUp handler can affect when it runs, as follows:

• To apply the handler to a specific sprite, put it in a sprite script.
• To apply the handler to a cast member in general, put it in a cast member script.
• To apply the handler to an entire frame, put it in a frame script.
• To apply the handler throughout the entire movie, put it in a movie script.

You can override an on mouseUp handler by placing an alternative on mouseUp handler in a location that Lingo checks before it gets to the handler you want to override. For example, you can override an on mouseUp handler assigned to a cast member by placing an on mouseUp handler in a sprite script.

If used in a behavior, this event is passed the sprite script or frame script reference me.
Example

This handler, assigned to sprite 10, switches the cast member assigned to sprite 10 when the user releases the mouse button after clicking the sprite:

```)
-- Lingo syntax
on mouseUp
    sprite(10).member = member("Dimmed")
end

// JavaScript syntax
function mouseUp() {
    sprite(10).member = member("Dimmed");
}
```

See also

`on mouseDown (event handler)`

**on mouseUpOutside**

Usage

```)
-- Lingo syntax
on mouseUpOutside me
    statement(s)
end

// JavaScript syntax
function mouseUpOutside() {
    statement(s);
}
```

Description

System message and event handler; sent when the user presses the mouse button on a sprite but releases it (away from) the sprite.

Example

This statement plays a sound when the user clicks the mouse button over a sprite and then releases it outside the bounding rectangle of the sprite:

```)
-- Lingo syntax
on mouseUpOutside me
    sound(1).play(member("Professor Long Hair"))
end

// JavaScript syntax
function mouseUpOutside() {
    sound(1).play(member("Professor Long Hair"));
}
```

See also

`on mouseEnter, on mouseLeave, on mouseWithin`
on mouseWithin

Usage
-- Lingo syntax
on mouseWithin
  statement(s)
end

// JavaScript syntax
function mouseWithin() {
  statement(s);
}

Description
System message and event handler; contains statements that run when the mouse is within the active area of the sprite. The mouse button does not have to be pressed.

If the sprite is a bitmap cast member with the matte ink applied, the active area is the portion of the image that is displayed; otherwise, the sprite's bounding rectangle is the active area.

If used in a behavior, this event is passed the sprite script or frame script reference me.

Example
This statement displays the mouse location when the mouse pointer is over a sprite:

-- Lingo syntax
on mouseWithin
  member("Display").text = string(_mouse.mouseH)
end

// JavaScript syntax
function mouseWithin() {
  member("Display").text = _mouse.mouseH.toString();
}

See also
on mouseEnter, on mouseLeave

on moveWindow

Usage
-- Lingo syntax
on moveWindow
  statement(s)
end

// JavaScript syntax
function moveWindow() {
  statement(s);
}

Description
System message and event handler; contains statements that run when a window is moved, such as by dragging a movie to a new location on the Stage, and is a good place to put Lingo that you want executed every time a movie's window changes location.
Example
This handler displays a message in the Message window when the window a movie is playing in moves:

-- Lingo syntax
on moveWindow
    put("Just moved window containing " && _movie.name)
end

// JavaScript syntax
function moveWindow() {
    put("Just moved window containing "+_movie.name);
}

See also
activeWindow, name (3D), windowList

on openWindow

Usage

-- Lingo syntax
on openWindow
    statement(s)
end

// JavaScript syntax
function openWindow() {
    statement(s);
}

Description
System message and event handler; contains statements that run when Director opens the movie as a movie in a window and is a good place to put Lingo that you want executed every time the movie opens in a window.

Example
This handler plays the sound file Hurray when the window that the movie is playing in opens:

-- Lingo syntax
on openWindow
    sound(2).play(member("Hurray"))
end

// JavaScript syntax
function openWindow() {
    sound(2).play(member("Hurray"));
}
on prepareFrame

Usage
-- Lingo syntax
on prepareFrame
  statement(s)
end

// JavaScript syntax
function prepareFrame()
  statement(s);
}

Description
System message and event handler; contains statements that run immediately before the current frame is drawn.

Unlike beginSprite and endSprite events, a prepareFrame event is generated each time the playhead enters a frame.

The on prepareFrame handler is a useful place to change sprite properties before the sprite is drawn.

If used in a behavior, the on prepareFrame handler receives the reference me.

The go, play, and updateStage commands are disabled in an on prepareFrame handler.

Example
This handler sets the locH property of the sprite that the behavior is attached to:

-- Lingo syntax
on prepareFrame me
  sprite(me.spriteNum).locH = _mouse.mouseH
end

// JavaScript syntax
function prepareFrame(){
  sprite(SpriteNum).locH = _mouse.mouseH;
}

See also
on enterFrame

on prepareMovie

Usage
-- Lingo syntax
on prepareMovie
  statement(s)
end

// JavaScript syntax
function prepareMovie()
  statement(s);
}
Description

System message and event handler; contains statements that run after the movie preloads cast members but before the movie does the following:

- Creates instances of behaviors attached to sprites in the first frame that plays.
- Prepares the first frame that plays, including drawing the frame, playing any sounds, and executing transitions and palette effects.

New global variables used for sprite behaviors in the first frame should be initialized in the on prepareMovie handler. Global variables already set by the previous movie do not need to be reset.

An on prepareMovie handler is a good place to put Lingo that creates global variables, initializes variables, plays a sound while the rest of the movie is loading into memory, or checks and adjusts computer conditions such as color depth.

The go, play, and updateStage commands are disabled in an on prepareMovie handler.

Example

This handler creates a global variable when the movie starts:

-- Lingo syntax
on prepareMovie
    global currentScore
    currentScore = 0
end

// JavaScript syntax
function prepareMovie() {
    _global.currentScore = 0;
}

See also

on enterFrame, on startMovie

on resizeWindow

Usage

-- Lingo syntax
on resizeWindow
    statement(s)
end

// JavaScript syntax
function resizeWindow() {
    statement(s);
}

Description

System message and event handler; contains statements that run when a movie is running as a movie in a window (MIAW) and the user resizes the window by dragging the window's resize box or one of its edges.

An on resizeWindow event handler is a good place to put Lingo related to the window's dimensions, such as Lingo that positions sprites or crops digital video.
Example

This handler moves sprite 3 to the coordinates stored in the variable `centerPlace` when the window that the movie is playing in is resized:

```-- Lingo syntax
on resizeWindow centerPlace
    sprite(3).loc = centerPlace
end
```

```// JavaScript syntax
function resizeWindow(centerPlace) {
    sprite(3).loc = centerPlace;
}
```

See also

drawRect, sourceRect

on rightMouseDown (event handler)

Usage

```-- Lingo syntax
on rightMouseDown
    statement(s)
end
```

```// JavaScript syntax
function rightMouseDown() {
    statement(s);
}
```

Description

System message and event handler; in Windows, specifies statements that run when the right mouse button is pressed. On Macintosh computers, the statements run when the mouse button and Control key are pressed simultaneously and the `emulateMultiButtonMouse` property is set to `TRUE`; if this property is set to `FALSE`, this event handler has no effect on the Macintosh.

Example

This handler opens the window Help when the user clicks the right mouse button in Windows:

```-- Lingo syntax
on rightMouseDown
    window("Help").open()
end
```

```// JavaScript syntax
function rightMouseDown() {
    window("Help").open();
}
```
on rightMouseUp (event handler)

Usage

-- Lingo syntax
on rightMouseUp
  statement(s)
end

// JavaScript syntax
function rightMouseUp() {
  statement(s);
}

Description

System message and event handler; in Windows, specifies statements that run when the right mouse button is released. On Macintosh computers, the statements run if the mouse button is released while the Control key is pressed and the emulateMultiButtonMouse property is set to TRUE; if this property is set to FALSE, this event handler has no effect on the Macintosh.

Example

This handler opens the Help window when the user releases the right mouse button in Windows:

-- Lingo syntax
on rightMouseUp
  window("Help").open()
end

// JavaScript syntax
function rightMouseUp() {
  window("Help").open();
}

on runPropertyDialog

Usage

-- Lingo syntax
on runPropertyDialog me, currentInitializerList
  statement(s)
end

// JavaScript syntax
function runPropertyDialog(currentInitializerList) {
  statement(s);
}

Description

System message and event handler; contains Lingo that defines specific values for a behavior’s parameters in the Parameters dialog box. The runPropertyDialog message is sent whenever the behavior is attached to a sprite, or when the user changes the initial property values of a sprite’s behavior.

The current settings for a behavior’s initial properties are passed to the handler as a property list. If the on runPropertyDialog handler is not defined within the behavior, Director runs a behavior customization dialog box based on the property list returned by the on getPropertyDescriptionList handler.
Example

The following handler overrides the behavior’s values set in the Parameters dialog box for the behavior. New values are contained in the list `currentInitializerList`. Normally, the Parameters dialog box allows the user to set the mass and gravitational constants. However, this handler assigns these parameters constant values without displaying a dialog box:

```-- Lingo syntax
property mass
property gravitationalConstant

on runPropertyDialog me, currentInitializerList
    -- force mass to 10
    currentInitializerList.setaProp(#mass, 10)
    -- force gravitationalConstant to 9.8
    currentInitializerList.setaProp(#gravitationalConstant, 9.8)
    return currentInitializerList
end
```

```// JavaScript syntax
function runPropertyDialog(currentInitializerList) {
    // force mass to 10
    currentInitializerList.setaProp("mass", 10)
    // force gravitationalConstant to 9.8
    currentInitializerList.setaProp("gravitationalConstant", 9.8)
    return(currentInitializerList)
}
```

on savedLocal

Usage

```-- Lingo syntax
on savedLocal
    statement(s)
end
```

```// JavaScript syntax
function savedLocal() {
    statement(s);
}
```

Description

System message and event handler; this property is provided to allow for enhancements in future versions of Shockwave Player.

See also

* allowSaveLocal
on sendXML

Usage

-- Lingo syntax
on sendXML "sendxmlstring", "window", "postdata"
  statement(s)
end

// JavaScript syntax
function sendXML(sendxmlstring, window, postdata) {
  statement(s);
}

Description

Event handler; functions much like the getURL scripting method, which is also available using the Macromedia Flash Asset Xtra extension. The on sendXML handler is called in Lingo when the XMLobject.send ActionScript method is executed in a Flash sprite or Flash XML object.

In ActionScript, the XMLobject.send method passes two parameters in addition to the XML data in the XML object. These parameters are as follows:

• uri—the URL to send the XML data to. Usually this is the URL of a server script that is waiting to process the XML data.
• window—the browser window in which to display the server's response data.

The ActionScript XMLobject.send method can be called in Director either by a Flash sprite or by a global Flash XML object created in Lingo. When this happens, the Lingo on sendXML handler is called, and the same parameters are passed to the handler.

The following Lingo illustrates how the parameters are received by the on sendXML handler:

on sendXML me, theURL, targetWindow, XMLdata

These parameters correlate with the XMLobject.send parameters as follows:

• theURL—the URL to send the XML data to.
• targetWindow—the browser window in which to display the server's response.
• XMLdata—the XML data in the Flash XML object.

By creating an on sendXML handler in your Director movie, you enable it to process XMLobject.send events generated in a Flash sprite or a global Flash object.

Flash sprites can also load external XML data or parse internal XML data. The Flash Asset Xtra extension handles these functions in the same way as Flash 5 or Flash MX content in your browser.

Example

This Lingo command gets the XMLobject.send method information from a Flash sprite and then directs the browser to the URL and transmits the XML data to the URL:

-- Lingo syntax
on sendXML me, theURL, targetWindow, xmlData
  gotoNetPage(theURL, targetWindow)
  postNetText(theURL, xmlData)
end
// JavaScript syntax
function sendXML(theURL, targetWindow, xmlData) {
    gotoNetPage(theURL, targetWindow);
    postNetText(theURL, xmlData);
}

on startMovie

Usage
-- Lingo syntax
on startMovie
    statement(s)
end

// JavaScript syntax
function startMovie() {
    statement(s);
}

Description
System message and event handler; contains statements that run just before the playhead enters the first frame of the movie. The startMovie event occurs after the prepareFrame event and before the enterFrame event.

An on startMovie handler is a good place to put Lingo that initializes sprites in the first frame of the movie.

Example
This handler makes sprites invisible when the movie starts:
-- Lingo syntax
on startMovie
    repeat with counter = 10 to 50
        sprite(counter).visible = 0
    end repeat
end startMovie

// JavaScript syntax
function startMovie() { 
    for(counter=10;counter<=50;counter++) {
        sprite(counter).visible = 0;
    }
}

See also
on prepareMovie
on stepFrame

Usage
-- Lingo syntax
on stepFrame
    statement(s)
end

// JavaScript syntax
function stepFrame() {
    statement(s);
}

Description

System message and event handler; works in script instances in actorList because these are the only objects that receive on stepFrame messages. This event handler is executed when the playhead enters a frame or the Stage is updated.

An on stepFrame handler is a useful location for Lingo that you want to run frequently for a specific set of objects. Assign the objects to actorList when you want Lingo in the on stepFrame handler to run; remove the objects from actorList to prevent Lingo from running. While the objects are in actorList, the objects’ on stepFrame handlers run each time the playhead enters a frame or the updateStage command is issued.

The stepFrame message is sent before the prepareFrame message.

Assign objects to actorList so they respond to stepFrame messages. Objects must have an on stepFrame handler to use this built-in functionality with actorList.

The go, play, and updateStage commands are disabled in an on stepFrame handler.

Example

If the child object is assigned to actorList, the on stepFrame handler in this parent script updates the position of the sprite that is stored in the mySprite property each time the playhead enters a frame:

-- Lingo syntax
property mySprite

on new me, theSprite
    mySprite = theSprite
    return me
end

on stepFrame me
    sprite(mySprite).loc = point(random(640),random(480))
end

// JavaScript syntax
// define a constructor class that contains the mySprite property
function Frame(theSprite) {
    this.mySprite = theSprite;
}

function stepFrame() {
    var myFrame = new Frame(sprite(spriteName).spriteNum);
    sprite(myFrame.mySprite).loc = point(random(640),random(480));
}
on stopMovie

Usage
-- Lingo syntax
on stopMovie
  statement(s)
end

// JavaScript syntax
function stopMovie() {
  statement(s);
}

Description
System message and event handler; contains statements that run when the movie stops playing.

An on stopMovie handler is a good place to put Lingo that performs cleanup tasks—such as closing resource files, clearing global variables, erasing fields, and disposing of objects—when the movie is finished.

An on stopMovie handler in a MIAW is called only when the movie plays through to the end or branches to another movie. It isn't called when the window is closed or when the window is deleted by the forget window command.

Example
This handler clears a global variable when the movie stops:

-- Lingo syntax
global gCurrentScore
on stopMovie
  gCurrentScore = 0
end

// JavaScript syntax
_global.gCurrentScore;
function stopMovie() {
  _global.gCurrentScore = 0;
}

See also
on prepareMovie

on streamStatus

Usage
-- Lingo syntax
on streamStatus URL, state, bytesSoFar, bytesTotal, error
  statement(s)
end

// JavaScript syntax
function streamStatus(URL, state, bytesSoFar, bytesTotal, error) {
  statement(s);
}
Description

System message and event handler; called periodically to determine how much of an object has been downloaded from the Internet. The handler is called only if `tellStreamStatus(TRUE)` has been called, and the handler has been added to a movie script.

The `on streamStatus` event handler has the following parameters:

- **URL**
  Displays the Internet address of the data being retrieved.

- **state**
  Displays the state of the stream being downloaded. Possible values are `Connecting`, `Started`, `InProgress`, `Complete`, and `Error`.

- **bytesSoFar**
  Displays the number of bytes retrieved from the network so far.

- **bytesTotal**
  Displays the total number of bytes in the stream, if known. The value may be 0 if the HTTP server does not include the content length in the MIME header.

- **error**
  Displays an empty string ("") if the download has not finished; OK (OK) if the download completed successfully; displays an error code if the download was unsuccessful.

These parameters are automatically filled in by Director with information regarding the progress of the download. The handler is called by Director automatically, and there is no way to control when the next call will be. If information regarding a particular operation is needed, call `getStreamStatus()`.

You can initiate network streams using Lingo commands, by linking media from a URL, or by using an external cast member from a URL. A `streamStatus` handler will be called with information about all network streams.

Place the `streamStatus` handler in a movie script.

Example

This handler determines the state of a streamed object and displays the URL of the object:

```lang
-- Lingo syntax
on streamStatus URL, state, bytesSoFar, bytesTotal
    if state = "Complete" then
        put(URL && "download finished")
    end if
end streamStatus

// JavaScript syntax
function streamStatus(URL, state, bytesSoFar, bytesTotal) {
    if (state == "Complete") {
        put(URL + " download finished");
    }
}
```

See also

`getStreamStatus()`, `tellStreamStatus()`
on timeOut

Usage

-- Lingo syntax
on timeOut
    statement(s)
end

// JavaScript syntax
function timeOut() {
    statement(s);
}

Description

System message and event handler; contains statements that run when the keyboard or mouse is not used for the time period specified in timeOutLength. Always place an on timeOut handler in a movie script.

To have a timeout produce the same response throughout a movie, use the timeoutScript to centrally control timeout behavior.

Example

The following handler plays the movie Attract Loop after users do nothing for the time set in the timeoutLength property. It can be used to respond when users leave the computer.

-- Lingo syntax
on timeOut
    _movie.play("Attract Loop")
end timeOut

// JavaScript syntax
function timeOut() {
    _movie.play("Attract Loop");
}

trayIconDoubleClick

Usage

-- Lingo syntax
on trayIconDoubleClick
    statement(s)
end

// JavaScript syntax
function trayIconDoubleClick() {
    statement(s);
}

Description

Movie and Window event handler (Microsoft Windows only). Contains statements that run when a user double-clicks the system tray icon.

The trayIconDoubleClick event is sent to the handler only if the systemTrayIcon property is set to TRUE.
Example

The following handler pauses a movie when a user double-clicks the system tray icon.

-- Lingo syntax
on trayIconDoubleClick
_movie.delay(500)
end

// JavaScript syntax
function trayIconDoubleClick() {
_movie.delay(500);
}

See also
Movie, systemTrayIcon, trayIconMouseDown, trayIconRightMouseDown, Window

trayIconMouseDown

Usage

-- Lingo syntax
on trayIconMouseDown
  statement(s)
end

// JavaScript syntax
function trayIconMouseDown() {
  statement(s);
}

Description

Movie and Window event handler (Microsoft Windows only). Contains statements that run when a user single-clicks the system tray icon.

The trayIconMouseDown event is sent to the handler only if the systemTrayIcon property is set to TRUE.

Example

The following handler pauses a movie when a user clicks the mouse when the mouse is over the system tray icon.

-- Lingo syntax
on trayIconMouseDown
_movie.delay(500)
end

// JavaScript syntax
function trayIconMouseDown() {
_movie.delay(500);
}

See also
Movie, systemTrayIcon, trayIconDoubleClick, trayIconRightMouseDown, Window
trayIconRightMouseDown

Usage
-- Lingo syntax
on trayIconRightMouseDown
  statement(s)
end

// JavaScript syntax
function trayIconRightMouseDown() {
  statement(s);
}

Description
Movie and Window event handler (Microsoft Windows only). Contains statements that run when a user right-clicks the system tray icon.

The `trayIconRightMouseDown` event is sent to the handler only if the `systemTrayIcon` property is set to `TRUE`.

Example
The following handler pauses a movie when a user right-clicks the system tray icon.

-- Lingo syntax
on trayIconRightMouseDown
  _movie.delay(500)
end

// JavaScript syntax
function trayIconRightMouseDown() {
  _movie.delay(500);
}

See also
Movie, systemTrayIcon, trayIconDoubleClick, trayIconMouseDown, Window

on zoomWindow

Usage
-- Lingo syntax
on zoomWindow
  statement(s)
end

// JavaScript syntax
function zoomWindow() {
  statement(s);
}

Description
System message and event handler; contains statements that execute whenever a movie running as a movie in a window (MIAW) is resized. This happens when the user clicks the Minimize or Maximize button (Windows) or the Zoom button (Macintosh). The operating system determines the dimensions after resizing the window.
An on zoomWindow event handler is a good place to put Lingo that rearranges sprites when window dimensions change.

Example

This handler moves sprite 3 to the coordinates stored in the variable centerPlace when the window that the movie is playing in is resized:

-- Lingo syntax
on zoomWindow
  centerPlace = point(10, 10)
  sprite(3).loc = centerPlace
end

// JavaScript syntax
function zoomWindow() {
  var centerPlace = point(10, 10);
  sprite(3).loc = centerPlace;
}

CHAPTER 11
Keywords

This section provides an alphabetical list of all the keywords available in Macromedia Director MX 2004.

These keywords apply only to Lingo. JavaScript syntax does contain some keywords and constructs that are similar in function to the following Lingo keywords, but they are not documented here. For more information about JavaScript syntax keywords and constructs, see Chapter 2, “Director Scripting Essentials,” on page 9.

\ (continuation)

Usage

-- Lingo syntax
first part of a statement on this line \ 
second part of the statement \ 
third part of the statement

Description

Continuation symbol; when used as the last character in a line, indicates that the statement continues on the next line. Lingo then interprets the lines as one continuous statement.

Example

This statement uses the \ character to wrap the statement onto two lines:

-- Lingo syntax
if sprite("mySprite").member = member("myMember") then \ 
_player.alert("The sprite was created from myMember")

case

Usage

-- Lingo syntax
case expression of
  expression1: Statement
  expression2: Statement(s)
  expression3, expression4: Statement
  [otherwise: Statement(s)]
end case
Description

Keyword; starts a multiple branching logic structure that is easier to write than repeated if...then statements.

Lingo compares the value in case expression to the expressions in the lines beneath it, starting at the beginning and continuing through each line in order, until Lingo encounters an expression that matches case expression.

When Lingo finds a matching expression, it executes the corresponding statement or statements that follow the colon after the matching expression. When only one statement follows the matching expression, the matching expression and its corresponding statement may appear on the same line. Multiple statements must appear on indented lines immediately below the matching expression.

When more than one possible match could cause Lingo to execute the same statements, the expressions must be separated by commas. (The syntax line containing expression3 and expression4 is an example of such a situation.)

After Lingo encounters the first match, it stops testing for additional matches.

If the optional otherwise statement is included at the end of the case structure, the statements following otherwise are executed if there are no matches.

Example

The following handler tests which key the user pressed most recently and responds accordingly.

- If the user pressed A, the movie goes to the frame labeled Apple.
- If the user pressed B or C, the movie performs the specified transition and then goes to the frame labeled Oranges.
- If the user pressed any other key, the computer beeps.

```lingo
on keyDown
  case (_key.key) of
    "a": _movie.go("Apple")
    "b", "c":
      _movie.puppetTransition(99)
      _movie.go("Oranges")
    otherwise: _sound.beep()
  end case
end keyDown
```

This case statement tests whether the cursor is over sprite 1, 2, or 3 and runs the corresponding Lingo if it is:

```lingo
case _movie.rollOver() of
  1: sound(1).play(member("Horn"))
  2: sound(1).play(member("Drum"))
  3: sound(1).play(member("Bongos"))
end case
```
char...of

Usage

-- Lingo syntax
textMemberExpression.char[whichCharacter]
char whichCharacter of fieldOrStringVariable
textMemberExpression.char[firstCharacter..lastCharacter]
char firstCharacter to lastCharacter of fieldOrStringVariable

Description

Keyword; identifies a character or a range of characters in a chunk expression. A chunk expression is any character, word, item, or line in any source of text (such as field cast members and variables) that holds a string.

• An expression using whichCharacter identifies a specific character.
• An expression using firstCharacter and lastCharacter identifies a range of characters.

The expressions must be integers that specify a character or range of characters in the chunk. Characters include letters, numbers, punctuation marks, spaces, and control characters such as Tab and Return.

You can test but not set the char...of keyword. Use the put...into command to modify the characters in a string.

Example

This statement displays the first character of the string $9.00:
put((("$9.00").char[1..1])
-- "$"

This statement displays the entire string $9.00:
put((("$9.00").char[1..5])
-- "$9.00"

This statement changes the first five characters of the second word in the third line of a text cast member:
member("quiz").line[3].word[2].char[1..5] = "?????"

See also

mouseMember, mouseItem, mouseLine, mouseWord
end

**Usage**

```lingo
-- Lingo syntax
end
```

**Description**

Keyword; marks the end of handlers and multiple-line control structures.

**Example**

The following `mouseDown` handler ends with an `end mouseDown` statement.

```lingo
on mouseDown
  _player.alert("The mouse was pressed")
end mouseDown
```

end case

**Usage**

```lingo
-- Lingo syntax
end case
```

**Description**

Keyword; ends a case statement.

**Example**

This handler uses the `end case` keyword to end the `case` statement:

```lingo
on keyDown
case (_key.key) of
  "a": _movie.go("Apple")
  "b", "c":
    _movie.puppetTransition(99)
    _movie.go("Oranges")
  otherwise: _sound.beep()
end case
end keyDown
```

**See also**

case

exit

**Usage**

```lingo
-- Lingo syntax
exit
```

**Description**

Keyword; instructs Lingo to leave a handler and return to where the handler was called. If the handler is nested within another handler, Lingo returns to the main handler.
Example

The first statement of this script checks whether the monitor is set to black and white and then exits if it is:

```script
on setColors
    if _system.colorDepth = 1 then exit
    sprite(1).foreColor = 35
end
```

See also

`abort, halt(), quit(), pass, return (keyword)`

exit repeat

Usage

-- Lingo syntax
exit repeat

Description

Keyword; instructs Lingo to leave a repeat loop and go to the statement following the `end repeat` statement but to remain within the current handler or method.

The `exit repeat` keyword is useful for breaking out of a repeat loop when a specified condition—such as two values being equal or a variable being a certain value—exists.

Example

The following handler searches for the position of the first vowel in a string represented by the variable `testString`. As soon as the first vowel is found, the `exit repeat` command instructs Lingo to leave the repeat loop and go to the statement `return i`:

```script
on findVowel testString
    repeat with i = 1 to testString.char[testString.char.count]
        if "aeiou" contains testString.char[i] then exit repeat
    end repeat
    return i
end
```

See also

`repeat while, repeat with`

field

Usage

`field(whichField)`

Description

Keyword; refers to the field cast member specified by `whichField`.

- When `whichField` is a string, it is used as the cast member name.
- When `whichField` is an integer, it is used as the cast member number.

Character strings and chunk expressions can be read from or placed in the field.
The term field was used in earlier versions of Director and is maintained for backward compatibility. For new movies, use member to refer to field cast members.

**Example**

This statement places the characters 5 through 10 of the field name entry in the variable myKeyword:

```javascript
myKeyword = field("entry").char[5..10]
```

This statement checks whether the user entered the word desk and, if so, goes to the frame deskBid:

```javascript
if member("bid") contains "desk" then _movie.go("deskBid")
```

**See also**

char...of, item...of, line...of, word...of

global

**Usage**

```
global variable1 [, variable2] [, variable3]...
```

**Description**

Keyword; defines a variable as a global variable so that other handlers or movies can share it.

Every handler that examines or changes the content of a global variable must use the global keyword to identify the variable as global. Otherwise, the handler treats the variable as a local variable, even if it is declared to be global in another handler.

**Note:** To ensure that global variables are available throughout a movie, declare and initialize them in the prepareMovie handler. Then, if you leave and return to the movie from another movie, your global variables will be reset to the initial values unless you first check to see that they aren’t already set.

A global variable can be declared in any handler or script. Its value can be used by any other handlers or scripts that also declare the variable as global. If the script changes the variable’s value, the new value is available to every other handler that treats the variable as global.

A global variable is available in any script or movie, regardless of where it is first declared; it is not automatically cleared when you navigate to another frame, movie, or window.

Any variables manipulated in the Message window are automatically global, even though they are not explicitly declared as such.

Movies with Macromedia Shockwave content playing on the Internet cannot access global variables within other movies, even movies playing on the same HTML page. The only way movies can share global variables is if an embedded movie navigates to another movie and replaces itself through either gotoNetMovie or go movie.

**Example**

The following example sets the global variable StartingPoint to an initial value of 1 if it doesn’t already contain a value. This allows navigation to and from the movie without loss of stored data.

```javascript
global gStartingPoint

on prepareMovie
  if voidP(gStartingPoint) then gStartingPoint = 1
end
```
See also

showGlobals(), property, gotoNetMovie

if

Usage

if logicalExpression then statement
if logicalExpression then statement
else statement
end if
if logicalExpression then
statement(s)
end if
if logicalExpression then
statement(s)
else
statement(s)
end if
if logicalExpression1 then
statement(s)
else if logicalExpression2 then
statement(s)
else if logicalExpression3 then
statement(s)
end if
if logicalExpression1 then
statement(s)
else logicalExpression2
end if

Description

Keyword; if...then structure that evaluates the logical expression specified by logicalExpression.

• If the condition is TRUE, Lingo executes the statement(s) that follow then.
• If the condition is FALSE, Lingo executes the statement(s) following else. If no statements follow else, Lingo exits the if...then structure.
• All parts of the condition must be evaluated; execution does not stop at the first condition that is met or not met. Thus, faster code may be created by nesting if...then statements on separate lines instead of placing them all on the first line to be evaluated.

When the condition is a property, Lingo automatically checks whether the property is TRUE. You don't need to explicitly add the phrase = TRUE after the property.

The else portion of the statement is optional. To use more than one then-statement or else-statement, you must end with the form end if.

The else portion always corresponds to the previous if statement; thus, sometimes you must include an else nothing statement to associate an else keyword with the proper if keyword.

Note: A quick way to determine in the script window if a script is paired properly is to press Tab. This forces Director to check the open Script window and show the indentation for the contents. Any mismatches will be immediately apparent.
Example

This statement checks whether the carriage return was pressed and then continues if it was:

\[
\text{if the key = RETURN then go the frame + 1}
\]

This handler checks whether the Command and Q keys were pressed simultaneously and, if so, executes the subsequent statements:

\[
\text{on keyDown}
\]
\[
\text{if (_key.commandDown) and (_key.key = "q") then}
\]
\[
\text{cleanUp}
\]
\[
\text{quit}
\]
\[
\text{end if}
\]
\[
\text{end keyDown}
\]

Compare the following two constructions and the performance results. The first construction evaluates both conditions, and so must determine the time measurement, which may take a while. The second construction evaluates the first condition; the second condition is checked only if the first condition is TRUE.

\[
\text{spriteUnderCursor = rollOver()}
\]
\[
\text{if (spriteUnderCursor > 25) and MeasureTimeSinceIStarted() then}
\]
\[
\text{_player.alert("You found the hidden treasure!")}
\]
\[
\text{end if}
\]

The alternate, and faster, construction would be as follows:

\[
\text{spriteUnderCursor = rollOver()}
\]
\[
\text{if (spriteUnderCursor > 25) then}
\]
\[
\text{if MeasureTimeSinceIStarted() then}
\]
\[
\text{_player.alert("You found the hidden treasure!")}
\]
\[
\text{end if}
\]
\[
\text{end if}
\]

See also

case

INF

Usage

\[
\text{-- Lingo syntax}
\]
\[
\text{INF}
\]

Description

Return value; indicates that a specified Lingo expression evaluates as an infinite number.

See also

NAN

item...of

Usage

\[
\text{-- Lingo syntax}
\]
\[
\text{textMemberExpression.item[whichItem]}
\]
\[
\text{item whichItem of fieldOrStringVariable}
\]
\[
\text{textMemberExpression.item[firstItem..lastItem]}
\]
\[
\text{item firstItem to lastItem of fieldOrStringVariable}
\]
Description

Keyword; specifies an item or range of items in a chunk expression. An item in this case is any sequence of characters delimited by the current delimiter as determined by the itemDelimiter property.

The terms whichItem, firstItem, and lastItem must be integers or integer expressions that refer to the position of items in the chunk.

Chunk expressions refer to any character, word, item, or line in any source of strings. Sources of strings include field and text cast members and variables that hold strings.

When the number that specifies the last item is greater than the item's position in the chunk expression, the actual last item is specified instead.

Example

This statement looks for the third item in the chunk expression that consists of names of colors and then displays the result in the Message window:

```
put("red,yellow,blue green,orange*.item[3])
-- "blue green"
```

The result is the entire chunk “blue green” because this is the entire chunk between the commas.

The following statement looks for the third through fifth items in the chunk expression. Because there are only four items in the chunk expression, only the third item is used and fourth items are returned. The result appears in the Message window.

```
put("red,yellow,blue green,orange*.item[3..5])
-- "blue green, orange"
```

The following statement inserts the item Desk as the fourth item in the second line of the field cast member All Bids:

```
member("All Bids").line[2].item[4] = "Desk"
```

See also

char...of, itemDelimiter, number of members, word...of

line...of

Usage

-- Lingo syntax

```
textMemberExpression.line[whichLine]
line whichLine of FieldOrStringVariable
textMemberExpression.line[firstLine..lastLine]
line firstLine to lastLine of FieldOrStringVariable
```

Description

Keyword; specifies a line or a range of lines in a chunk expression. A line chunk is any sequence of characters delimited by carriage returns, not by line breaks caused by text wrapping.

The expressions whichLine, firstLine, and lastLine must be integers that specify a line in the chunk.
Chunk expressions refer to any character, word, item, or line in any source of characters. Sources of characters include field cast members and variables that hold strings.

**Example**

This statement assigns the first four lines of the variable *Action* to the field cast member *To Do*:

```lingo
member("To Do").text = Action.line[1..4]
```

This statement inserts the word *and* after the second word of the third line of the string assigned to the variable *Notes*:

```lingo
put "and" after Notes.line[3].word[2]
```

**See also**

- `char...of`, `item...of`, `word...of`, `number of members`

### loop (keyword)

#### Usage

```lingo
-- Lingo syntax
_movie.goLoop()
```

#### Description

Keyword; refers to the marker.

**Example**

This handler loops the movie between the previous marker and the current frame:

```lingo
on exitFrame
_movie.goLoop()
end exitFrame
```

### me

#### Usage

```lingo
-- Lingo syntax
me
```

#### Description

Special variable; used within parent scripts and behaviors to refer to the current object that is an instance of the parent script or the behavior or a variable that contains the memory address of the object.

The term has no predefined meaning in Lingo. The term *me* is used by convention.

To see an example of *me* used in a completed movie, see the Parent Scripts movie in the Learning/Lingo Examples folder inside the Director application folder.

**Example**

The following statement sets the object *myBird1* to the script named *Bird*. The *me* keyword accepts the parameter script *Bird* and is used to return that parameter.

```lingo
myBird1 = new script("Bird")
```

This is the *on new* handler of the *Bird* script:
The following two sets of handlers make up a parent script. The first set uses `me` to refer to the child object. The second set uses the variable `myAddress` to refer to the child object. In all other respects, the parent scripts are the same.

This is the first set:

```lingo
property myData

on new me, theData
    myData = theData
    return me
end

on stepFrame me
    ProcessData me
end
```

This is the second set:

```lingo
property myData

on new myAddress, theData
    myData = theData
    return myAddress
end

on stepFrame myAddress
    ProcessData myAddress
end
```

See also

- `new()`, `ancestor`

**menu**

**Usage**

```lingo
-- Lingo syntax
menu: menuName

<table>
<thead>
<tr>
<th>ItemName</th>
<th>script</th>
</tr>
</thead>
<tbody>
<tr>
<td>ItemName</td>
<td>script</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>
```

or

```lingo
menu: menuName

<table>
<thead>
<tr>
<th>ItemName</th>
<th>script</th>
</tr>
</thead>
<tbody>
<tr>
<td>ItemName</td>
<td>script</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>
```

[more menus]

**Description**

Keyword; in conjunction with the `installMenu` command, specifies the actual content of custom menus. Field cast members contain menu definitions; refer to them by the cast member name or number.
The **menu** keyword is followed immediately by a colon, a space, and the name of the menu. In subsequent lines, specify the menu items for that menu. You can set a script to execute when the user chooses an item by placing the script after the vertical bar symbol (|). A new menu is defined by the subsequent occurrence of the **menu** keyword.

**Note:** Menus are not available in Shockwave Player.

On the Macintosh, you can use special characters to define custom menus. These special characters are case-sensitive. For example, to make a menu item bold, the letter **B** must be uppercase.

Special symbols should follow the item name and precede the vertical bar symbol (|). You can also use more than one special character to define a menu item. Using `<B><U>`, for example, sets the style to Bold and Underline.

Avoid special character formatting for cross-platform movies because not all Windows computers support it.

### Symbol Example Description

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@</td>
<td>menu: @</td>
<td>*On the Macintosh, creates the Apple symbol and enables Macintosh menu bar items when you define an Apple menu.</td>
</tr>
<tr>
<td>!A</td>
<td>!A Easy Select</td>
<td>*On the Macintosh, checks the menu with a check mark (Option+v).</td>
</tr>
<tr>
<td>&lt;B</td>
<td>Bold&gt;&lt;B</td>
<td>*On the Macintosh, sets the menu item's style to Bold.</td>
</tr>
<tr>
<td>&lt;I</td>
<td>Italic&gt;&lt;I</td>
<td>*On the Macintosh, sets the style to Italic.</td>
</tr>
<tr>
<td>&lt;U</td>
<td>Underline&gt;&lt;U</td>
<td>*On the Macintosh, sets the style to Underline.</td>
</tr>
<tr>
<td>&lt;O</td>
<td>Outline&gt;&lt;O</td>
<td>*On the Macintosh, sets the style to Outline.</td>
</tr>
<tr>
<td>&lt;S</td>
<td>Shadow&gt;&lt;S</td>
<td>*On the Macintosh, sets the style to Shadow.</td>
</tr>
<tr>
<td></td>
<td>Open/O</td>
<td>go to frame &quot;Open&quot;</td>
</tr>
<tr>
<td>/</td>
<td>Quit/Q</td>
<td>Defines a command-key equivalent.</td>
</tr>
<tr>
<td>\</td>
<td>Save\</td>
<td>Disables the menu item.</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
<td>Creates a disabled line in the menu.</td>
</tr>
</tbody>
</table>

* identifies formatting tags that work only on the Macintosh.

**Example**

This example is the text of a field cast member named CustomMenu2 which can be used to specify the content of a custom File menu. To install this menu, use `installMenu member("CustomMenu2")` while the movie is running. The Convert menu item runs the custom handler `convertThis`.

```plaintext
menu: File
Open/O | _movie.go("Open")
Close/W | _movie.go("Close")
Convert/C | convertThis
- Quit/Q | _movie.go("Quit")
```

**See also**

`installMenu, name, number (menu items), checkMark, enabled, script`
**NAN**

**Usage**

```-- Lingo syntax
NAN
```

**Description**

Return value; Indicates that a specified Lingo expression is not a number.

This statement attempts to display the square root of -1, which is not a number, in the Message window:

```-- Lingo syntax
put((-1).sqrt) -- NAN
```

**See also**

INF

**next**

**Usage**

```-- Lingo syntax
next
```

**Description**

Keyword; refers to the next marker in the movie and is equivalent to the phrase `the marker (+ 1)`.

**Example**

This statement sends the playhead to the next marker in the movie:

```go next
```

This handler moves the movie to the next marker in the Score when the right arrow key is pressed and to the previous marker when the left arrow key is pressed:

```on keyUp
  if (_key.keyCode = 124) then _movie.goNext()
  if (_key.keyCode = 123) then _movie.goPrevious()
end keyUp
```

**See also**

`loop (keyword), goPrevious()`
**next repeat**

**Usage**

```
-- Lingo syntax
next repeat
```

**Description**

Keyword; sends Lingo to the next step in a repeat loop in a script. This function differs from that of the `exit repeat` keyword.

**Example**

This repeat loop displays only odd numbers in the Message window:

```lingo
repeat with i = 1 to 10
    if (i mod 2) = 0 then next repeat
    put(i)
end repeat
```

**on**

**Usage**

```
-- Lingo syntax
on handlerName {argument1}, {arg2}, {arg3} ...
    statement(s)
end handlerName
```

**Description**

Keyword; indicates the beginning of a handler, a collection of Lingo statements that you can execute by using the handler name. A handler can accept arguments as input values and returns a value as a function result.

Handlers can be defined in behaviors, movie scripts, and cast member scripts. A handler in a cast member script can be called only by other handlers in the same script. A handler in a movie script can be called from anywhere.

You can use the same handler in more than one movie by putting the handler’s script in a shared cast.

**otherwise**

**Usage**

```
-- Lingo syntax
otherwise statement(s)
```

**Description**

Keyword; precedes instructions that Lingo performs when none of the earlier conditions in a `case` statement are met.

This keyword can be used to alert users of out-of-bound input or invalid type, and can be very helpful in debugging during development.
Example

The following handler tests which key the user pressed most recently and responds accordingly:

• If the user pressed A, B, or C, the movie performs the corresponding action following the `of` keyword.
• If the user pressed any other key, the movie executes the statement that follows the `otherwise` keyword. In this case, the statement is a simple alert.

```lingo
on keyDown
  case (_key.key) of
    "a": _movie.go("Apple")
    "b", "c":
      _movie.puppetTransition(99)
      _movie.go("Oranges")
  otherwise: _player.alert("That is not a valid key.")
  end case
end keyDown
```

property

Usage

-- Lingo syntax
property {property1}{, property2} {,property3} {...}

Description

Keyword; declares the properties specified by `property1`, `property2`, and so on as property variables.

Declare property variables at the beginning of the parent script or behavior script. You can access them from outside the parent script or behavior script by using the `the` operator.

Note: The `spriteNum` property is available to all behaviors and simply needs to be declared to be accessed.

You can refer to a property within a parent script or behavior script without using the `me` keyword. However, to refer to a property of a parent script's ancestor, use the form `me.property`.

For behaviors, properties defined in one behavior script are available to other behaviors attached to the same sprite.

You can directly manipulate a child object's property from outside the object's parent scripts through syntax similar to that for manipulating other properties. For example, this statement sets the `motionStyle` property of a child object:

```lingo
set the motionStyle of myBouncingObject to #frenetic
```

Use the `count` function to determine the number of properties within the parent script of a child object. Retrieve the name of these properties by using `getPropAt`. Add properties to an object by using `setaProp()`.

To see an example of `property` used in a completed movie, see the Parent Scripts movie in the Learning/Lingo Examples folder inside the Director application folder.

Example

This statement lets each child object created from a single parent script have its own location and velocity setting:

```lingo
property location, velocity
```
This parent script handler declares `pMySpriteNum` a property to make it available:

```lingo
-- script Elder
property pMyChannel
on new me, whichSprite
    me.pMyChannel = whichSprite
    return me
end
```

The original behavior script sets up the ancestor and passes the `spriteNum` property to all behaviors:

```lingo
property spriteNum
property ancestor
on beginSprite me
    ancestor = new script("Elder", spriteNum)
end
```

See also

`me`, `ancestor`, `spriteNum`

**put...after**

**Usage**

-- Lingo syntax

```lingo
put expression after chunkExpression
```

**Description**

Command; evaluates a Lingo expression, converts the value to a string, and inserts the resulting string after a specified chunk in a container, without replacing the container's contents. (If `chunkExpression` specifies a nonexistent target chunk, the string value is inserted as appropriate into the container.)

Chunk expressions refer to any character, word, item, or line in any container. Containers include field cast members; text cast members; variables that hold strings; and specified characters, words, items, lines, and ranges within containers.

**Example**

This statement adds the string “fox dog cat” after the contents of the field cast member Animal List:

```lingo
put("fox dog cat") after member("Animal List")
```

The same can be accomplished using this statement:

```lingo
put "fox dog cat" after member("Animal List").line[1]
```

See also

`char...of`, `item...of`, `line...of`, `paragraph`, `word...of`, `put...before`, `put...into`
put...before

Usage
-- Lingo syntax
put expression before chunkExpression

Description
Command; evaluates a Lingo expression, converts the value to a string, and inserts the resulting string before a specified chunk in a container, without replacing the container's contents. (If chunkExpression specifies a nonexistent target chunk, the string value is inserted as appropriate into the container.)

Chunk expressions refer to any character, word, item, or line in any container. Containers include field cast members; text cast members; variables that hold strings; and specified characters, words, items, lines, and ranges in containers.

Example
This statement sets the variable animalList to the string “fox dog cat” and then inserts the word elk before the second word of the list:
put "fox dog cat" into animalList
put "elk " before word 2 of animalList

The result is the string “fox elk dog cat”.

The same can be accomplished using this syntax:
put "fox dog cat" into animalList
put "elk " before animalList.word[2]

See also
char...of, item...of, line...of, paragraph, word...of, put...after, put...into

put...into

Usage
-- Lingo syntax
put expression into chunkExpression

Description
Command; evaluates a Lingo expression, converts the value to a string, and uses the resulting string to replace a specified chunk in a container. (If chunkExpression specifies a nonexistent target chunk, the string value is inserted as appropriate into the container.)

Chunk expressions refer to any character, word, item, or line in any container. Containers include field cast members; text cast members; variables that hold strings; and specified characters, words, items, lines, and ranges in containers.

When a movie plays back as an applet, the put...into command replaces all text within a container, not chunks of text.

To assign values to variables, use the set command.
**Example**

This statement changes the second line of the field cast member Review Comments to “Reviewed by Agnes Gooch”:

```lingo
put "Reviewed by Agnes Gooch" into line 2 of member("Review Comments")
```

The same can be accomplished with a text cast member using this syntax:

```lingo
put "Reviewed by Agnes Gooch" into member("Review Comments").line[2]
```

**See also**

`char...of, item...of, line...of, paragraph, word...of, put...before, put...after, set...to, set...=`

---

**repeat while**

**Usage**

```lingo
-- Lingo syntax
repeat while testCondition
    statement(s)
end repeat
```

**Description**

Keyword; repeatedly executes statement(s) so long as the condition specified by testCondition is TRUE. This structure can be used in Lingo that continues to read strings until the end of a file is reached, checks items until the end of a list is reached, or repeatedly performs an action until the user presses or releases the mouse button.

While in a repeat loop, Lingo ignores other events. To check the current key in a repeat loop, use the keyPressed property.

Only one handler can run at a time. If Lingo stays in a repeat loop for a long time, other events stack up waiting to be evaluated. Therefore, repeat loops are best used for short, fast operations or when users are idle.

If you need to process something for several seconds or more, evaluate the function in a loop with some type of counter or test to track progress.

If the stop condition is never reached or there is no exit from the repeat loop, you can force Director to stop by using Control+Alt+period (Windows) or Command+period (Macintosh).

**Example**

This handler starts the timer counting, resets the timer to 0, and then has the timer count up to 60 milliseconds:

```lingo
on countTime
    _system.milliseconds = 0
    repeat while _system.milliseconds < 60
        -- waiting for time
    end repeat
end countTime
```

**See also**

`exit, exit repeat, repeat with, keyPressed()`
repeat with

Usage

-- Lingo syntax  
repeat with counter = start to finish  
  statement(s)  
end repeat

Description

Keyword; executes the Lingo specified by statement(s) the number of times specified by counter. The value of counter is the difference between the value specified by start and the value specified by finish. The counter is incremented by 1 each time Lingo cycles through the repeat loop.

The repeat with structure is useful for repeatedly applying the same effect to a series of sprites or for calculating a series of numbers to some exponent.

While in a repeat loop, Lingo ignores other events. To check the current key in a repeat loop, use the keyPressed property.

Only one handler can run at a time. If Lingo stays in a repeat loop for a long time, other events stack up waiting to be evaluated. Therefore, repeat loops are best used for short, fast operations or when users are idle.

If you need to process something for several seconds or more, evaluate the function in a loop with some type of counter or test to track progress.

If the stop condition is never reached or there is no exit from the repeat loop, you can force Director to stop by using Control+Alt+period (Windows) or Command+period (Macintosh).

Example

This handler turns sprites 1 through 30 into puppets:

on puppetize  
  repeat with channel = 1 to 30  
    _movie.puppetSprite(channel, TRUE)  
  end repeat  
end puppetize

See also

exit, exit repeat, repeat while, repeat with...down to, repeat with...in list

repeat with...down to

Usage

-- Lingo syntax  
repeat with variable = startValue down to endValue

Description

Keyword; counts down by increments of 1 from startValue to endValue.

Only one handler can run at a time. If Lingo stays in a repeat loop for a long time, other events stack up waiting to be evaluated. Therefore, repeat loops are best used for short, fast operations or when you know the user won't be doing other things.
While in a repeat loop, Lingo ignores other events. To check the current key in a repeat loop, use the `keyPressed` property.

If you need to process something for several seconds or more, evaluate the function in a loop with some type of counter or test to track progress.

If the stop condition is never reached or there is no exit from the repeat loop, you can force Director to stop by using Control+Alt+period (Windows) or Command+period (Macintosh).

**Example**

This handler contains a repeat loop that counts down from 20 to 15:

```
on countDown
  repeat with i = 20 down to 15
    sprite(6).member = 10 + i
    _movie.updateStage()
  end repeat
end
```

**repeat with...in list**

**Usage**

```
-- Lingo syntax
repeat with variable in someList
```

**Description**

Keyword; assigns successive values from the specified list to the variable.

While in a repeat loop, Lingo ignores other events except keypresses. To check the current key in a repeat loop, use the `keyPressed` property.

Only one handler can run at a time. If Lingo stays in a repeat loop for a long time, other events stack up waiting to be evaluated. Therefore, repeat loops are best used for short, fast operations or when users are idle.

If you need to process something for several seconds or more, evaluate the function in a loop with some type of counter or test to track progress.

If the stop condition is never reached or there is no exit from the repeat loop, you can force Director to stop by using Control+Alt+period (Windows) or Command+period (Macintosh).

**Example**

This statement displays four values in the Message window:

```
repeat with i in [1, 2, 3, 4]
  put(i)
end repeat
```
**return (keyword)**

**Usage**

```lingo
-- Lingo syntax
return expression
```

**Description**

Keyword; returns the value of `expression` and exits from the handler. The `expression` argument can be any Lingo value.

When calling a handler that serves as a user-defined function and has a return value, you must use parentheses around the argument lists, even if there are no arguments, as in the `diceRoll` function handler discussed under the entry for the `result` function.

The function of the `return` keyword is similar to that of the `exit` command, except that `return` also returns a value to whatever called the handler. The `return` command in a handler immediately exits from that handler, but it can return a value to the Lingo that called it.

The use of `return` in object-oriented scripting can be difficult to understand. It's easier to start by using `return` to create functions and exit handlers. Later, you will see that the `return me` line in an `on new` handler gives you a way to pass back a reference to an object that was created so it can be assigned to a variable name.

The `return` keyword isn't the same as the character constant `RETURN`, which indicates a carriage return. The function depends on the context.

To retrieve a returned value, use parentheses after the handler name in the calling statement to indicate that the named handler is a function.

To see an example of `return (keyword)` used in a completed movie, see the Parent Scripts movie in the Learning/Lingo Examples folder inside the Director application folder.

**Example**

This handler returns a random multiple of 5 between 5 and 100:

```
on getRandomScore
  theScore = 5 * random(20)
  return theScore
end getRandomScore
```

Call this handler with a statement similar to the following:

```
thisScore = getRandomScore()
```

In this example, the variable `thisScore` is assigned the return value from the function `getRandomScore()`. A parent script performs the same function: by returning the object reference, the variable name in the calling code provides a handle for subsequent references to that object.

**See also**

`result`, `RETURN (constant)`
set...to, set...=

Usage

-- Lingo syntax

lingoProperty = expression
variable = expression

Description

Command; evaluates an expression and puts the result in the property specified by
lingoProperty or the variable specified by variable.

Example

This statement sets the name of member 3 to Sunset:

member(3).name = "Sunset"

The following statement sets the soundEnabled property to the opposite of its current state.
When soundEnabled is TRUE (the sound is on), this statement turns it off. When soundEnabled
is FALSE (the sound is off), this statement turns it on.

_sound.soundEnabled = not(_sound.soundEnabled)

This statement sets the variable vowels to the string “aeiou”:

vowels = "aeiou"

See also

property

sprite...intersects

Usage

-- Lingo syntax

sprite(sprite1).intersects(sprite2)
sprite sprite1 intersects sprite2

Description

Keyword; operator that compares the position of two sprites to determine whether the quad of
sprite1 touches (TRUE) or does not touch (FALSE) the quad of sprite2.

If both sprites have matte ink, their actual outlines, not the quads, are used. A sprite’s outline is
defined by the nonwhite pixels that make up its border.

This is a comparison operator with a precedence level of 5.

Note: The dot operator is required whenever sprite1 is not a simple expression—that is, one that
contains a math operation.

Example

This statement checks whether two sprites intersect and, if they do, changes the contents of the
field cast member Notice to “You placed it correctly”:

if sprite i intersects j then put("You placed it correctly.") \
into member("Notice")

See also

sprite...within, quad
sprite...within

Usage

-- Lingo syntax
sprite(spritel).within(sprite2)
sprite spritel within sprite2

Description

Keyword; operator that compares the position of two sprites and determines whether the quad of
sprite1 is entirely inside the quad of sprite2 (TRUE) or not (FALSE).

If both sprites have matte ink, their actual outlines, not the quads, are used. A sprite's outline is
defined by the nonwhite pixels that make up its border.

This is a comparison operator with a precedence level of 5.

Note: The dot operator is required whenever spritel is not a simple expression—that is, one that
contains a math operation.

Example

This statement checks whether two sprites intersect and calls the handler doInside if they do:
if sprite(3).within(2) then doInside

See also

sprite...intersects, quad

version

Usage

-- Lingo syntax
_player.productVersion

Description

Keyword; system variable that contains the version string for Director. The same string appears in
the Macintosh Finder's Info window.

Example

This statement displays the version of Director in the Message window:
put(_player.productVersion)
**word...of**

**Usage**

```
-- Lingo syntax
member(whichCastMember).word[whichWord]
textMemberExpression.word[whichWord]
chunkExpression.word[whichWord]
fieldOrStringVariable.word[whichWord]
textMemberExpression.word[firstWord..lastWord]
member(whichCastMember).word[firstWord..lastWord]
word firstWord to lastWord of chunkExpression
chunkExpression.word[whichWord..lastWord]
```

**Description**

Chunk expression; specifies a word or a range of words in a chunk expression. A word chunk is any sequence of characters delimited by spaces. (Any non-visible character, such as a tab or carriage return, is considered a space.)

The expressions `whichWord`, `firstWord`, and `lastWord` must evaluate to integers that specify a word in the chunk.

Chunk expressions refer to any character, word, item, or line in any source of characters. Sources of characters include field and text cast members and variables that hold strings.

To see an example of `word...of` used in a completed movie, see the Text movie in the Learning/Lingo Examples folder inside the Director application folder.

**Example**

These statements set the variable named `animalList` to the string “fox dog cat” and then insert the word `elk` before the second word of the list:

```
animalList = "fox dog cat"
put "elk" before animalList.word[2]
```

The result is the string “fox elk dog cat”.

This statement tells Director to display the fifth word of the same string in the Message window:

```
put "fox elk dog cat".word[5]
```

Because there is no fifth word in this string, the Message window displays two quotation marks (""), which indicate an empty string.

**See also**

`char...of`, `line...of`, `item...of`, `count()`, `number (words)`
This section provides an alphabetical list of all the methods available in Director.

**abort**

**Usage**

--Lingo syntax
abort

// JavaScript syntax
abort();

**Description**

Command; tells Lingo to exit the current handler and any handler that called it without executing any of the remaining statements in the handler. This differs from the `exit` keyword, which returns to the handler from which the current handler was called.

The `abort` command does not quit Director.

**Parameters**

None.

**Example**

This statement instructs Lingo to exit the handler and any handler that called it when the amount of free memory is less than 50K:

-- Lingo syntax
if the freeBytes < 50*1024 then abort

// JavaScript syntax
if (_player.freeBytes < 50*1024) {
    abort();
}

**See also**

`exit`, `halt()`, `quit()`
abs()

Usage
-- Lingo syntax
abs (numericExpression)

// JavaScript syntax
Math.abs (numericExpression)

Description
Math function (Lingo only); calculates the absolute value of a numerical expression.
The abs() function has several uses. It can simplify the tracking of mouse and sprite movement
by converting coordinate differences (which can be either positive or negative numbers) into
distances (which are always positive numbers). The abs() function is also useful for handling
mathematical functions, such as sqrt() and log().
In JavaScript syntax, use the Math object’s abs() function.

Parameters
numericExpression Required. An integer or floating-point number from which an absolute
value is calculated. If numericExpression is an integer, the absolute value is also an integer. If
numericExpression is a floating-point number, the absolute value is also a floating-point
number.

Example
This statement determines whether the absolute value of the difference between the current
mouse position and the value of the variable startV is greater than 30 (since you wouldn’t want
to use a negative number for distance). If it is, the foreground color of sprite 6 is changed.
-- Lingo syntax
if (the mouseV - startV).abs > 30 then sprite(6).forecolor = 95

// JavaScript syntax
if ((_mouse.mouseV - Math.abs(_mouse.startV)) > 30) {
   sprite(6).foreColor = 95;
}

activateAtLoc()

Usage
-- Lingo syntax
dvdObjRef.activationAtLoc(point(x, y))

// JavaScript syntax
dvdObjRef.activationAtLoc(point(x, y));

Description
DVD method; activates the hilite of the embedded DVD menu item that is under a specified
Stage location.
This method returns 0 if successful.
Parameters

point(x, y) Required. A point that specifies the location of the embedded DVD menu item.

Example

This statement activates the hilite of the menu item at a specified Stage location:

-- Lingo syntax
member("movie1").activateAtLoc(point(100, 200))

// JavaScript syntax
member("movie1").activateAtLoc(point(100, 200));

See also

DVD

activateButton()

Usage

-- Lingo syntax
dvdObjRef.activateButton()

// JavaScript syntax
dvdObjRef.activateButton();

Description

DVD method; activates the currently selected menu button.
This method returns 0 if successful.

Parameters

None.

Example

This statement activates the menu button on a specified cast member:

-- Lingo syntax
sprite(1).member.activateButton()

// JavaScript syntax
sprite(1).member.activateButton();

See also

DVD
add

Usage

-- Lingo syntax
linearList.add(value)

// JavaScript syntax
array.push(value)

Description

List command; for linear lists only, adds a value to a linear list. For a sorted list, the value is placed in its proper order. For an unsorted list, the value is added to the end of the list.

This command returns an error when used on a property list.

Note: Don’t confuse the add command with the + operator used for addition or the & operator used to concatenate strings.

Parameters

value Required. A value to add to the linear list.

Example

These statements add the value 2 to the list named bids. The resulting list is [3, 4, 1, 2].

-- Lingo syntax
bids = [3, 4, 1]
bids.add(2)

// JavaScript syntax
bids = new Array(3,4,1);
bids.push(2);

This statement adds 2 to the sorted linear list [1, 4, 5]. The new item remains in alphanumeric order because the list is sorted.

-- Lingo syntax
bids.add(2)

// JavaScript syntax
bids.push(2);
// to sort the list using JavaScript syntax
bids.sort();

See also

textureLayer.add()

add (3D texture)

Usage

-- Lingo syntax
member(whichCastmember).model(whichModel).meshdeform.mesh[index].
   textureLayer.add()

// JavaScript syntax
member(whichCastmember).model(whichModel).meshdeform.mesh[index].
   textureLayer.add()
Description

3D meshdeform modifier command; adds an empty texture layer to the model's mesh.

You can copy texture coordinates between layers using the following code:

```lingo
modelReference.meshdeform.texturelayer[a].texturecoordinatelist = modelReference.meshdeform.texturelayer[b].texturecoordinatelist
```

Parameters

None.

Example

This statement creates a new texture layer for the first mesh of the model named Ear.

```lingo
member("Scene").model("Ear").meshdeform.mesh[1].textureLayer.add()
```

```javascript
member("Scene").model("Ear").meshdeform.mesh[1].textureLayer.add();
```

See also

meshDeform (modifier), textureLayer, textureCoordinateList

addAt

Usage

`list.AddAt(position, value)`

Description

List command; for linear lists only, adds a value at a specified position in the list.

This command returns an error when used with a property list.

Parameters

- `position` Required. An integer that specifies the position in the list to which the value specified by `value` is added.
- `value` Required. A value to add to the list.

Example

This statement adds the value 8 to the fourth position in the list named `bids`, which is `[3, 2, 4, 5, 6, 7]`:

```lingo
bids = [3, 2, 4, 5, 6, 7]
bids.addAt(4, 8)
```

The resulting value of `bids` is `[3, 2, 4, 8, 5, 6, 7]`. 
addBackdrop

Usage
-- Lingo syntax
sprite(whichSprite).camera(index).addBackdrop(texture, locWithinSprite, rotation)
member(whichCastmember).camera(whichCamera).addBackdrop(texture, locWithinSprite, rotation)

// JavaScript syntax
sprite(whichSprite).camera(index).addBackdrop(texture, locWithinSprite, rotation);
member(whichCastmember).camera(whichCamera).addBackdrop(texture, locWithinSprite, rotation);

Description
3D camera command; adds a backdrop to the end of the camera's list of backdrops.

Parameters

texture Required. The texture to apply to the backdrop.

locWithinSprite Required. A 2D loc at which the backdrop is displayed in the 3D sprite. This location is measured from the upper left corner of the sprite.

rotation Required. An integer that specifies the number of degrees to rotate the texture.

Example
The first line of this statement creates a texture named Rough from the cast member named Cedar and stores it in the variable t1. The second line applies the texture as a backdrop at the point (220, 220) within sprite 5. The texture has a rotation of 0 degrees. The last line applies the same texture as a backdrop for camera 1 of the cast member named Scene at the point (20, 20) with a rotation of 45 degrees.

t1 = member("Scene").newTexture("Rough", #fromCastMember, \
    member("Cedar"))
sprite(5).camera.addBackdrop(t1, point(220, 220), 0)
member("Scene").camera[1].addBackdrop(t1, point(20, 20), 45)

See also
removeBackdrop

addCamera

Usage
-- Lingo syntax
sprite(whichSprite).addCamera(whichCamera, index)

-- JavaScript syntax
sprite(whichSprite).addCamera(whichCamera, index);

Description
3D command; adds a camera to the list of cameras for the sprite. The view from each camera is displayed on top of the view from cameras with lower index positions. You can set the rect property of each camera to display multiple views within the sprite.
Parameters

**whichCamera** Required. A reference to the camera to add to the list of cameras for the sprite.

**index** Required. An integer that specifies the index in the list of cameras at which **whichCamera** is added. If **index** is greater than the value of **cameraCount()**, the camera is added to the end of the list.

Example

This statement inserts the camera named FlightCam at the fifth index position of the list of cameras of sprite 12:

```--Lingo syntax
sprite(12).addCamera(member("scene").camera("FlightCam"), 5)
```

```// JavaScript syntax
sprite(12).addCamera(member("scene").camera("FlightCam"), 5);
```

See also

**cameraCount()**, **deleteCamera**

addChild

Usage

```-- Lingo syntax
member(whichCastmember).node(whichParentNode).addChild(member\(whichCastmember).node(whichChildNode) {,\#preserveWorld})
```

```// JavaScript syntax
member(whichCastmember).node(whichParentNode).addChild(member\(whichCastmember).node(whichChildNode) {,symbol(preserveWorld))}
```

Description

3D command; adds a node to the list of children of another node, and removes it from the list of children of its former parent.

An equivalent to this method would be to set the **parent** property of the child node to the parent node.

Parameters

**addMemberRef** Required. A reference to the cast member that contains the node to add.

**addNodeRef** Required. A reference to the node to add. This node can be a model, group, camera, or light.

**symPreserveParentOrWorld** Optional. A reference to the camera to add to the list of cameras for the sprite. Valid values are **#preserveWorld** or **#preserveParent**. When the child is added with **#preserveParent** specified, the parent-relative transform of the child remains unchanged and the child jumps to that transform in the space of its new parent. The child's world transform is recalculated. When the child is added with **#preserveWorld** specified, the world transform of the child remains unchanged and the child does not jump to its transform in the space of its new parent. Its parent-relative transform is recalculated.
Example

This statement adds the model named Tire to the list of children of the model named Car.

-- Lingo syntax
member("3D").model("Car").addChild(member("3D").model("Tire"))

// JavaScript syntax
member("3D").model("Car").addChild(member("3D").model("Tire"));

This statement adds the model named Bird to the list of children of the camera named MyCamera and uses the #preserveWorld argument to maintain Bird’s world position.

-- Lingo syntax
member("3D").camera("MyCamera").addChild(member("3D").model("Bird"), #preserveWorld)

// JavaScript syntax
member("3D").camera("MyCamera").addChild(member("3D").model("Bird"), symbol("preserveWorld"));

See also

parent, addToWorld, removeFromWorld

addModifier

Usage

-- Lingo syntax
member(whichCastmember).model(whichModel).addModifier(#modifierType)

// JavaScript syntax
member(whichCastmember).model(whichModel).addModifier(symbol(modifierType));

Description

3D model command; adds a specified modifier to the model. There is no default value for this command.

Parameters

symbolModType Required. A symbol that specifies the modifier to add. Possible modifiers are as follows:

- #bonesPlayer
- #collision
- #inker
- #keyframePlayer
- #lod (level of detail)
- #meshDeform
- #sds
- #toon

For more detailed information about each modifier, see the individual modifier entries.
Example

This statement adds the toon modifier to the model named Box.

-- Lingo syntax
member("shapes").model("Box").addModifier(#toon)

// JavaScript syntax
member("shapes").model("Box").addModifier(symbol("toon"));

See also
bonesPlayer (modifier), collision (modifier), inker (modifier), keyframePlayer (modifier), lod (modifier), meshDeform (modifier), sds (modifier), toon (modifier), getRendererServices(), removeModifier, modifier, modifier[], modifiers

addOverlay

Usage

-- Lingo syntax
sprite(whichSprite).camera(index).addOverlay(texture, locWithinSprite, rotation)
member(whichCastmember).camera(whichCamera).addOverlay(texture, locWithinSprite, rotation)

// JavaScript syntax
sprite(whichSprite).camera(index).addOverlay(texture, locWithinSprite, rotation)
member(whichCastmember).camera(whichCamera).addOverlay(texture, locWithinSprite, rotation)

Description

3D camera command; adds an overlay to the end of a camera's list of overlays.

Parameters

texture Required. The texture to apply to the overlay.
locWithinSprite Required. A 2D loc at which the overlay is displayed in the 3D sprite. This location is measured from the upper left corner of the sprite.
rotation Required. An integer that specifies the number of degrees to rotate the texture.

Example

The first line of this statement creates a texture named Rough from the cast member named Cedar and stores it in the variable t1. The second line applies the texture as an overlay at the point (220, 220) within sprite 5. The texture has a rotation of 0 degrees. The last line of the statement applies the same texture as an overlay for camera 1 of the cast member named Scene at the point (20, 20). The texture has a rotation of 45 degrees.

-- Lingo syntax
t1 = member("Scene").newTexture("Rough", #fromCastMember, member("Cedar"))
sprite(5).camera.addOverlay(t1, point(220, 220), 0)
member("Scene").camera[1].addOverlay(t1, point(20, 20), 45)
addProp

Usage

list.addProp(property, value)
addProp list, property, value

Description

Property list command; for property lists only, adds a specified property and its value to a property list.

For an unsorted list, the value is added to the end of the list. For a sorted list, the value is placed in its proper order.

If the property already exists in the list, both Lingo and JavaScript syntax create a duplicate property. You can avoid duplicate properties by using the setaProp() command to change the new entry's property.

This command returns an error when used with a linear list.

Parameters

property Required. The property to add to the list.
value Required. The value of the property to add to the list.

Example

This statement adds the property named kayne and its assigned value 3 to the property list named bids, which contains [#gee: 4, #ohasi: 1]. Because the list is sorted, the new entry is placed in alphabetical order:
bids.addProp(#kayne, 3)

The result is the list [#gee: 4, #kayne: 3, #ohasi: 1].

This statement adds the entry kayne: 7 to the list named bids, which now contains [#gee: 4, #kayne: 3, #ohasi: 1]. Because the list already contains the property kayne, Lingo creates a duplicate property:
bids.addProp(#kayne, 7)

The result is the list [#gee: 4, #kayne: 3, #kayne: 7, #ohasi: 1].

See also

removeOverlay
addToWorld

Usage
-- Lingo syntax
member(whichCastmember).model(whichModel).addToWorld()
member(whichCastmember).group(whichGroup).addToWorld()
member(whichCastmember).camera(whichCamera).addToWorld()
member(whichCastmember).light(whichLight).addToWorld()

// JavaScript syntax
member(whichCastmember).model(whichModel).addToWorld()
member(whichCastmember).group(whichGroup).addToWorld()
member(whichCastmember).camera(whichCamera).addToWorld()
member(whichCastmember).light(whichLight).addToWorld()

Description
3D command; inserts the model, group, camera, or light into the 3D world of the cast member as a child of the group named World.

When a model, group, camera, or light is created or cloned, it is automatically added to the world. Use the removeFromWorld command to take a model, group, camera, or light out of the 3D world without deleting it. Use the isInWorld() command to test whether a model, group, camera, or light has been added or removed from the world.

Parameters
None.

Example
This statement adds the model named gbCyl to the 3D world of the cast member named Scene.

-- Lingo syntax
member("Scene").model("gbCyl").addToWorld()

// JavaScript syntax
member("Scene").model("gbCyl").addToWorld();

See also
isInWorld(), removeFromWorld

addVertex()

Usage
-- Lingo syntax
memberObjRef.addVertex(indexToAddAt, pointToAddVertex [, [ horizControlLocV, \ vertControlLocV ], [ horizControlLocH, vertControlLocV ]])

// JavaScript syntax
memberObjRef.addVertex(indexToAddAt, pointToAddVertex [, [ horizControlLocV, \ vertControlLocV ], [ horizControlLocH, vertControlLocV ]]);

Description
Vector shape command; adds a new vertex to a vector shape cast member in the position specified.

The horizontal and vertical positions are relative to the origin of the vertex shape cast member.
When using the final two optional parameters, you can specify the location of the control handles for the vertex. The control handle location is offset relative to the vertex, so if no location is specified, it will be located at 0 horizontal offset and 0 vertical offset.

**Parameters**

- `indexToAddAt` Required. An integer that specifies the index at which the member is added.
- `pointToAddVertex` Required. A point that specifies the position at which the member is added.
- `horizControlLocH` Optional. An integer that specifies the location of the horizontal portion of the horizontal control handle.
- `horizControlLocV` Optional. An integer that specifies the location of the vertical portion of the horizontal control handle.
- `vertControlLocH` Optional. An integer that specifies the location of the horizontal portion of the vertical control handle.
- `vertControlLocV` Optional. An integer that specifies the location of the vertical portion of the vertical control handle.

**Example**

This line adds a vertex point in the vector shape Archie between the two existing vertex points, at the position 25 horizontal and 15 vertical:

-- Lingo syntax
member("Archie").addVertex(2, point(25, 15))

// JavaScript syntax
member("Archie").addVertex(2, point(25, 15));

**See also**

`vertexList`, `moveVertex()`, `deleteVertex()`, `originMode`

---

**alert()**

**Usage**

-- Lingo syntax
_player.alert(displayString)

// JavaScript syntax
_player.alert(displayString);

**Description**

Player method; causes a system beep and displays an alert dialog box containing a specified string. The alert message must be a string. If you want to include a number variable in an alert, convert the variable to a string before passing it to `alert()`.

**Parameters**

- `displayString` Required. A string that represents the text displayed in the alert dialog box. The string can contain up to 255 characters.
Example

The following statement produces an alert stating that there is no CD-ROM drive connected:

-- Lingo syntax
_player.alert("There is no CD-ROM drive connected.");

// JavaScript syntax
_player.alert("There is no CD-ROM drive connected.");

This statement produces an alert stating that a file was not found:

-- Lingo syntax
_player.alert("The file" & QUOTE & filename & QUOTE & " was not found.");

// JavaScript syntax
_player.alert("The file \\
" + filename + " was not found.");

See also

Player

append

Usage

list.append(value)
append list, value

Description

List command; for linear lists only, adds the specified value to the end of a linear list. This differs from the add command, which adds a value to a sorted list according to the list's order.

This command returns a script error when used with a property list.

Properties

value Required. The value to add to the end of the linear list.

Example

This statement adds the value 2 at the end of the sorted list named bids, which contains [1, 3, 4], even though this placement does not match the list's sorted order:

set bids = [1, 3, 4]
bids.append(2)

The resulting value of bids is [1, 3, 4, 2].

See also

add (3D texture), sort
appMinimize()

Usage
-- Lingo syntax
_player.appMinimize()

// JavaScript syntax
_player.appMinimize();

Description
Player method; in Microsoft Windows, causes a projector to minimize to the Windows Task Bar. On the Macintosh, causes a projector to be hidden.

On the Macintosh, reopen a hidden projector from the Macintosh application menu.
This method is useful for projectors and MIAW's that play back without a title bar.

Parameters
None.

Example
--Lingo syntax
on mouseUp me
_player.appMinimize()
end

// JavaScript syntax
function mouseUp() {
_player.appMinimize();
}

See also
Player

atan()

Usage
-- Lingo syntax
(number).atan
atan (number)

// JavaScript syntax
Math.atan(number);

Description
Math function (Lingo only); calculates the arctangent, which is the angle whose tangent is a specified number. The result is a value in radians between pi/2 and +pi/2.

In JavaScript syntax, use the Math object's atan() function.

Parameters
None.
Example

This statement displays the arctangent of 1:

(1).atan

The result, to four decimal places, is 0.7854, or approximately pi/4.

Most trigonometric functions use radians, so you may want to convert from degrees to radians. This handler lets you convert between degrees and radians:

-- Lingo syntax
on DegreesToRads degreeValue
    return degreeValue * PI/180
end

// JavaScript syntax
function DegreesToRads(degreeValue) {
    return degreeValue * PI/180
}

The handler displays the conversion of 30 degrees to radians in the Message window:

put DegreesToRads(30)  -- 0.5236

See also
cos(), PI, sin()

beep()

Usage

-- Lingo syntax
_sound.beep({intBeepCount})

// JavaScript syntax
_sound.beep({intBeepCount});

Description

Sound method; causes the computer's speaker to beep the number of times specified by intBeepCount. If intBeepCount is missing, the beep occurs once.

• In Windows, the beep is the sound assigned in the Sounds Properties dialog box.
• For the Macintosh, the beep is the sound selected from Alert Sounds on the Sound control panel. If the volume on the Sound control panel is set to 0, the menu bar flashes instead.

Parameters

intBeepCount Optional. An integer that specifies the number of times the computer's speakers should beep.

Example

-- Lingo syntax
on mouseUp me
    _sound.beep(1)
end mouseUp
// JavaScript syntax
function mouseUp() {
    _sound.beep(1);
}

See also
Sound

beginRecording()

Usage
-- Lingo syntax
_movie.beginRecording()

// JavaScript syntax
_movie.beginRecording();

Description
Movie method; starts a Score generation session.

When you call `beginRecording()`, the playhead automatically advances one frame and begins recording in that frame. To avoid this behavior and begin recording in the frame in which `beginRecording()` is called, place a statement such as `_movie.go(_movie.frame - 1)` between the calls to `beginRecording()` and `endRecording()`.

Only one update session in a movie can be active at a time.

Every call to `beginRecording()` must be matched by a call to `endRecording()`, which ends the Score generation session.

Parameters
None.

Example
When used in the following handler, the `beginRecording` keyword begins a Score generation session that animates the cast member Ball by assigning the cast member to sprite channel 20 and then moving the sprite horizontally and vertically over a series of frames. The number of frames is determined by the argument `numberOfFrames`.

-- Lingo syntax
on animBall(numberOfFrames)
    _movie.beginRecording()
    horizontal = 0
    vertical = 100
    repeat with i = 1 to numberOfFrames
        _movie.go(i)
        _sprite(20).member = member("Ball")
        _sprite(20).locH = horizontal
        _sprite(20).locV = vertical
        _sprite(20).foreColor = 255
        horizontal = horizontal + 3
    end repeat
    _movie.endRecording()
end animBall
// JavaScript syntax
function animBall(numberOfFrames) {
    _movie.beginRecording();
    var horizontal = 0;
    var vertical = 100;
    for (var i = 1; i <= numberOfFrames; i++) {
        _movie.go(1);
        sprite(20).member = member("Ball");
        sprite(20).locH = horizontal;
        sprite(20).locV = vertical;
        horizontal = horizontal + 3;
        vertical = vertical + 2;
        _movie.updateFrame();
    }
    _movie.endRecording();
}

See also
endRecording(), Movie

bitAnd()

Usage
bitAnd(integer1, integer2)

Description
Function (Lingo only); converts the two specified integers to 32-bit binary numbers and returns a
binary number whose digits are 1’s in the positions where both numbers had a 1, and 0’s in every
other position. The result is the new binary number, which Lingo displays as a base 10 integer.

<table>
<thead>
<tr>
<th>Integer</th>
<th>Binary number (abbreviated)</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>00110</td>
</tr>
<tr>
<td>7</td>
<td>00111</td>
</tr>
</tbody>
</table>

Result

<table>
<thead>
<tr>
<th></th>
<th>00110</th>
</tr>
</thead>
</table>

In JavaScript syntax, use the bitwise operator "&".

Parameters

integer1 Required. The first integer.

integer2 Required. The second integer.

Example

This statement compares the binary versions of the integers 6 and 7 and returns the result as an
integer:

put bitAnd(6, 7)

-- 6

See also

bitNot(), bitOr(), bitXor()
bitNot()

Usage
(bitNot(integer)).bitNot
bitNot(integer)

Description
Function (Lingo only); converts the specified integer to a 32-bit binary number and reverses the value of each binary digit, replacing 1's with 0's and 0's with 1's. The result is the new binary number, which Lingo displays as a base 10 integer.

<table>
<thead>
<tr>
<th>Integer</th>
<th>Binary number</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>00000000000000000000000000000001</td>
</tr>
<tr>
<td>-2</td>
<td>11111111111111111111111111111110</td>
</tr>
</tbody>
</table>

In JavaScript syntax, use the bitwise operator "~".

Parameters
None.

Example
This statement inverts the binary representation of the integer 1 and returns a new number.
put (1).bitNot
-- -2

See also
bitAnd(), bitOr(), bitXor()

bitOr()

Usage
bitOr(integer1, integer2)

Description
Function (Lingo only); converts the two specified integers to 32-bit binary numbers and returns a binary number whose digits are 1's in the positions where either number had a 1, and 0's in every other position. The result is the new binary number, which Lingo displays as a base 10 integer.

<table>
<thead>
<tr>
<th>Integer</th>
<th>Binary number (abbreviated)</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>0101</td>
</tr>
<tr>
<td>6</td>
<td>0110</td>
</tr>
<tr>
<td>7</td>
<td>0111</td>
</tr>
</tbody>
</table>

In JavaScript syntax, use the bitwise operator "|".
Parameters

integer1 Required. The first integer.
integer2 Required. The second integer.

Example

This statement compares the 32-bit binary versions of 5 and 6 and returns the result as an integer:
```
put bitOr(5, 6)
-- 7
```

See also

bitNot(), bitAnd(), bitXor()

bitXor()

Usage

bitXor(integer1, integer2)

Description

Function; converts the two specified integers to 32-bit binary numbers and returns a binary number whose digits are 1's in the positions where the given numbers' digits do not match, and 0's in the positions where the digits are the same. The result is the new binary number, which Lingo displays as a base 10 integer.

<table>
<thead>
<tr>
<th>Integer</th>
<th>Binary number (abbreviated)</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>0101</td>
</tr>
<tr>
<td>6</td>
<td>0110</td>
</tr>
</tbody>
</table>

Result

| 3       | 0011                        |

In JavaScript syntax, use the bitwise operator "^".

Parameters

integer1 Required. The first integer.
integer2 Required. The second integer.

Example

This statement compares the 32-bit binary versions of 5 and 6 and returns the result as an integer:
```
put bitXor(5, 6)
-- 3
```

See also

bitNot(), bitOr(), bitAnd()
breakLoop()

Usage
--- Lingo syntax
soundChannelObjRef.breakLoop()

// JavaScript syntax
soundChannelObjRef.breakLoop();

Description
Sound Channel method; causes the currently looping sound in channel soundChannelObjRef to stop looping and play through to its endTime.
If there is no current loop, this method has no effect.

Parameters
None.

Example
This handler causes the background music looping in sound channel 2 to stop looping and play through to its end:
--- Lingo syntax
on continueBackgroundMusic
    sound(2).breakLoop()
end

// JavaScript syntax
function continueBackgroundMusic() {
    sound(2).breakLoop();
}

See also
d endTime, Sound Channel

browserName()

Usage
browserName pathName
browserName()
browserName(#enabled, trueOrFalse)

Description
System property, command, and function; specifies the path or location of the browser. You can use the FileIO Xtra to display a dialog box that allows the user to search for a browser. The displayOpen() method of the FileIO Xtra is useful for displaying an Open dialog box.

The form browserName() returns the name of the currently specified browser. Placing a pathname, like one found using the FileIO Xtra, as an argument in the form browserName(fullPathToApplication) allows the property to be set. The form browserName(#enabled, trueOrFalse) determines whether the specified browser launches automatically when the goToNetPage command is issued.
This command is only useful playing back in a projector or in Director, and has no effect when playing back in a browser.

This property can be tested and set.

Example

This statement refers to the location of the Netscape browser:

```
browserName "My Disk:My Folder:Netscape"
```

This statement displays the browser name in a Message window:

```
put browserName()
```

### build()

**Usage**

```
member(whichCastmember).modelResource(whichModelResource).build()
```

```
member(whichCastmember).modelResource(whichModelResource).build();
```

**Description**

3D mesh command; constructs a mesh. This command is only used with model resources whose type is #mesh.

You must use the `build()` command in the initial construction of the mesh, after changing any of the face properties of the mesh, and after using the `generateNormals()` command.

**Parameters**

None.

**Example**

This example creates a simple model resource whose type is #mesh, specifies its properties, and then creates a new model using the model resource. The process is outlined in the following line-by-line explanation of the example code:

Line 1 creates a mesh called Plane, which has one face, three vertices, and a maximum of three colors. The number of normals and the number of texture coordinates are not set. The normals are created by the `generateNormals` command.

Line 2 defines the vectors that will be used as the vertices for Plane.

Line 3 assigns the vectors to the vertices of the first face of Plane.

Line 4 defines the three colors allowed by the `newMesh` command.

Line 5 assigns the colors to the first face of Plane. The third color in the color list is applied to the first vertex of Plane, the second color to the second vertex, and the first color to the third vertex. The colors will spread across the first face of Plane in gradients.

Line 6 creates the normals of Plane with the `generateNormals()` command.
Line 7 calls the build() command to construct the mesh.

```lingo
-- Lingo syntax
nm = member("Shapes").newMesh("Plane",1,3,0,3,0)
nm.vertexList = [vector(0,0,0), vector(20,0,0), vector(20, 20, 0)]
nm.face[1].vertices = [1,2,3]
nm.colorList = [rgb(255,255,0), rgb(0, 255, 0), rgb(0,0,255)]
nm.face[1].colors = [3,2,1]
nm.generateNormals(#smooth)
nm.build()
nm = member("Shapes").newModel("TriModel", nm)
```

// JavaScript syntax
```javascript
nm = member("Shapes").newMesh("Plane",1,3,0,3,0);
nm.vertexList = [vector(0,0,0), vector(20,0,0), vector(20, 20, 0)];
nm.face[1].vertices = [1,2,3];
nm.colorList = [rgb(255,255,0), rgb(0, 255, 0), rgb(0,0,255)];
nm.face[1].colors = [3,2,1];
nm.generateNormals(#smooth);
nm.build();
nm = member("Shapes").newModel("TriModel", nm);
```

See also
generateNormals(), newMesh, face[]

cacheDocVerify()

Usage

```
-- Lingo syntax
cacheDocVerify #setting
cacheDocVerify()
```

// JavaScript syntax
```javascript
cacheDocVerify symbol(setting);
cacheDocVerify();
```

Description

Function; sets how often the contents of a page on the Internet are refreshed with information from the projector's cache.

The form `cacheDocVerify()` returns the current setting of the cache.

The `cacheDocVerify` function is valid only for movies running in Director or as projectors. This function is not valid for movies with Macromedia Shockwave content because they use the network settings of the browser in which they run.

```
-- Lingo syntax
on resetCache
current = cacheDocVerify()
if current = #once then
    alert "Turning cache verification on"
cacheDocVerify #always
end if
end
```
// JavaScript syntax
function resetCache() {
    current = cacheDocVerify();
    if (current == symbol("once")) {
        alert("Turning cache verification on");
        cacheDocVerify(symbol("always"));
    }
}

Parameters

*cacheSetting* Optional. A symbol that specifies how often the contents of a page on the Internet are refreshed. Possible values are *once* (default) and *always*. Specifying *once* tells a movie to get a file from the Internet once and then use the file from the cache without looking for an updated version on the Internet. Specifying *always* tells a movie to try to get an updated version of the file each time the movie calls a URL.

See also

cacheSize(), clearCache

**cacheSize()**

Usage

-- Lingo syntax
cacheSize Size

// JavaScript syntax
cacheSize(Size);

cacheSize();

Description

Function and command; sets the cache size of Director.

The `cacheSize` function is valid only for movies running in Director or as projectors. This function is not valid for movies with Shockwave content because they use the network settings of the browser in which they run.

Parameters

*newCacheSize* Optional. An integer that specifies the cache size, in kilobytes.

Example

This handler checks whether the browser’s cache setting is less than 1 MB. If it is, the handler displays an alert and sets the cache size to 1 MB:

-- Lingo syntax
on checkCache if
    cacheSize()<1000 then
        alert "Increasing cache to 1MB"
        cacheSize 1000
    end if
end

// JavaScript syntax
function resetCache() {
    current = cacheDocVerify();
    if (current == symbol("once")) {
        alert("Turning cache verification on");
        cacheDocVerify(symbol("always"));
    }
}
// JavaScript syntax
function checkCache() {
  if (cacheSize() < 1000) {
    alert("Increasing cache to 1MB");
    cacheSize(1000);
  }
}

See also
cacheDocVerify(), clearCache

call

Usage

call #handlerName, script, {args...}
call (#handlerName, scriptInstance, {args...})

Description

Command; sends a message that invokes a handler in a specified script or list of scripts.
The call command can use a variable as the name of the handler. Messages passed using call are not passed to other scripts attached to the sprite, cast member scripts, frame scripts, or movie scripts.

Parameters

_symHandlerName_ Required. A symbol that specifies the handler to activate.

_scriptInstance_ Required. A reference to the script or list of scripts that contains the handler. If _scriptInstance_ is a single script instance, an error alert occurs if the handler is not defined in the script's ancestor script. If _scriptInstance_ is a list of script instances, the message is sent to each item in the list in turn; if the handler is not defined in the ancestor script, no alert is generated.

_args_ Optional. Any optional parameters to be passed to the handler.

Example

This handler sends the message bumpCounter to the first behavior script attached to sprite 1:

-- Lingo syntax
on mouseDown me
  -- get the reference to the first behavior of sprite 1
  set xref = getAt (the scriptInstanceList of sprite 1, 1)
  -- run the bumpCounter handler in the referenced script, with a parameter
  call (#bumpCounter, xref, 2)
end

// JavaScript syntax
function mouseDown() {
  // get the reference to the first behavior of sprite 1
  xref = getAt(s sprite(1).script(1));
  // run the bumpCounter handler in the referenced script
  call(symbol("bumpcounter"), xref, 2);
}
The following example shows how a call statement can call handlers in a behavior or parent script and its ancestor.

• This is the parent script:

```lingo
-- Lingo syntax
-- script Man
property ancestor
on new me
    set ancestor = new(script "Animal", 2)
    return me
end
on run me, newTool
    put "Man running with \"&\the legCount of me\" legs"
end
```

• This is the ancestor script:

```lingo
-- script Animal
property legCount
on new me, newLegCount
    set legCount = newLegCount
    return me
end
on run me
    put "Animal running with \"& legCount &\" legs"
end
on walk me
    put "Animal walking with \"& legCount &\" legs"
end
```

• The following statements use the parent script and ancestor script.

This statement creates an instance of the parent script:

```
set m = new(script "man")
```

This statement makes the man walk:

```
call #walk, m
-- "Animal walking with 2 legs"
```

This statement makes the man run:

```
set msg = #run
call msg, m
-- "Man running with 2 legs and rock"
```

This statement creates a second instance of the parent script:

```
set m2 = new(script "man")
```

This statement sends a message to both instances of the parent script:

```
call msg, [m, m2]
-- "Man running with 2 legs"
-- "Man running with 2 legs"
```
callAncestor

Usage

callAncestor handlerName, script, {args...}

Description

Command; sends a message to a child object's ancestor script.

Ancestors can, in turn, have their own ancestors.

When you use callAncestor, the name of the handler can be a variable, and you can explicitly bypass the handlers in the primary script and go directly to the ancestor script.

Parameters

symHandlerName Required. A symbol that specifies the handler to activate.

scriptInstance Required. A reference to the script or list of scripts that contains the handler.

If scriptInstance is a single script instance, an error alert occurs if the handler is not defined in the script's ancestor script. If scriptInstance is a list of script instances, the message is sent to each item in the list in turn; if the handler is not defined in the ancestor script, no alert is generated.

args Optional. Any optional parameters to be passed to the handler.

Example

This example shows how a callAncestor statement can call handlers in the ancestor of a behavior or parent script.

• This is the parent script:
  -- script "man"
  property ancestor
  on new me, newTool
    set ancestor = new(script "Animal", 2)
    return me
  end
  on run me
    put "Man running with "&the legCount of me&" legs"
  end

• This is the ancestor script:
  -- script "animal"
  property legCount
  on new me, newLegCount
    set legCount = newLegCount
    return me
  end
  on run me
    put "Animal running with "& legCount &" legs"
  end
  on walk me
    put "Animal walking with "& legCount &" legs"
  end

• The following statements use the parent script and ancestor script.
  This statement creates an instance of the parent script:
  set m = new(script "man")
This statement makes the man walk:
```
call #walk, m
-- "Animal walking with 2 legs"
```

This statement makes the man run:
```
set msg = #run
callAncestor msg, m
-- "Animal running with 2 legs"
```

This statement creates a second instance of the parent script:
```
set m2 = new(script "man")
```

This statement sends a message to the ancestor script for both men:
```
callAncestor #run,[m,m2]
-- "Animal running with 2 legs"
-- "Animal running with 2 legs"
```

See also
```
ancestor, new()
```

callFrame()

Usage
```
-- Lingo syntax
spriteObjRef.callFrame(flashFrameNameOrNum)

// JavaScript syntax
spriteObjRef.callFrame(flashFrameNameOrNum);
```

Description
Command; used to call a series of actions that reside in a frame of a Flash movie sprite.
This command sends a message to the Flash ActionScript engine and triggers the actions to execute in the Flash movie.

Parameters

- `flashFrameNameOrNum` Required. A string or number that specifies the name or number of the frame to call.

Example
This Lingo executes the actions that are attached to frame 10 of the Flash movie in sprite 1:
```
-- Lingo syntax
sprite(1).callFrame(10)

// JavaScript syntax
sprite(1).callFrame(10);
```
camera()

Usage

member(whichCastMember).camera(whichCamera)
member(whichCastMember).camera[index]
member(whichCastMember).camera(whichCamera).whichCameraProperty
member(whichCastMember).camera[index].whichCameraProperty
sprite(whichSprite).camera[[index]].whichCameraProperty

Description

3D element; an object at a vector position from which the 3D world is viewed.

Each sprite has a list of cameras. The view from each camera in the list is displayed on top of the view from camera with lower index positions. You can set the rect (camera) property of each camera to display multiple views within the sprite.

Cameras are stored in the camera palette of the cast member. Use the newCamera and deleteCamera commands to create and delete cameras in a 3D cast member.

The camera property of a sprite is the first camera in the list of cameras of the sprite. The camera referred to by sprite(whichSprite).camera is the same as sprite(whichSprite).camera(1). Use the addCamera and deleteCamera commands to build the list of cameras in a 3D sprite.

Example

This statement sets the camera of sprite 1 to the camera named TreeCam of the cast member named Picnic.

sprite(1).camera = member("Picnic").camera("TreeCam")

This statement sets the camera of sprite 1 to camera 2 of the cast member named Picnic.

sprite(1).camera = member("Picnic").camera[2]

See also

bevelDepth, overlay, modelUnderLoc, spriteSpaceToWorldSpace, fog, clearAtRender

cameraCount()

Usage

-- Lingo syntax
sprite(whichSprite).cameraCount()

// JavaScript syntax
sprite(whichSprite).cameraCount();

Description

3D command; returns the number items in the list of cameras of the sprite.

Parameters

None.
Example
This statement shows that sprite 5 contains three cameras.
-- Lingo syntax
put sprite(5).cameraCount()
-- 3

// JavaScript syntax
put (sprite(5).cameraCount());
// 3

See also
addCamera, deleteCamera

cancelIdleLoad()

Usage
-- Lingo syntax
_movie.cancelIdleLoad(intLoadTag)

// JavaScript syntax
_movie.cancelIdleLoad(intLoadTag);

Description
Movie method; cancels the loading of all cast members that have the specified load tag.

Parameters
intLoadTag Required. An integer that specifies a group of cast members that have been queued for loading when the computer is idle.

Example
This statement cancels the loading of cast members that have an idle load tag of 20:
-- Lingo syntax
_movie.cancelIdleLoad(20)

// JavaScript syntax
_movie.cancelIdleLoad(20);

See also
idleLoadTag, Movie

castLib()

Usage
-- Lingo syntax
castLib(castNameOrNum)

// JavaScript syntax
castLib(castNameOrNum);

Description
Top level function; returns a reference to a specified cast library.
The default cast library number is 1. To specify a cast member in a cast library other than cast 1, set `castLib()` to specify the alternative cast library.

**Parameters**

- `castNameOrNum` Required. A string that specifies the cast library name, or an integer that specifies the cast library number.

**Example**

This statement sets the variable `parts` to the second cast library:

---

- **Lingo syntax**
  ```lingo
casts = castLib(2)
  ```

- **JavaScript syntax**
  ```javascript
  var parts = castLib(2);
  ```

**See also**

- [Cast Library](#)
- [castLibNum](#)

---

### channel() (Top level)

**Usage**

- **Lingo syntax**
  ```lingo
  channel(soundChannelNameOrNum)
  ```

- **JavaScript syntax**
  ```javascript
  channel(soundChannelNameOrNum);
  ```

**Description**

Top level function; returns a reference to a Sound Channel object.

**Parameters**

- `soundChannelNameOrNum` Required. A string that specifies the name of a sound channel, or an integer that specifies the index position of a sound channel.

**Example**

This statement sets the variable `newChannel` to sound channel 9:

---

- **Lingo syntax**
  ```lingo
  newChannel = channel(9)
  ```

- **JavaScript syntax**
  ```javascript
  var newChannel = channel(9);
  ```

**See also**

- [Sound Channel](#)
channel() (Sound)

Usage

-- Lingo syntax
_sound.channel(intChannelNum)

// JavaScript syntax
_sound.channel(intChannelNum);

Description

Sound method; returns a reference to a specified sound channel.

The functionality of this method is identical to the top level sound() method.

Parameters

intChannelNum Required. An integer that specifies the sound channel to reference.

Example

This statement sets the variable named myChannel to sound channel 2:

-- Lingo syntax
myChannel = _sound.channel(2)

// JavaScript syntax
var myChannel = _sound.channel(2);

See also

Sound, sound(), Sound Channel

chapterCount()

Usage

-- Lingo syntax
dvdObjRef.chapterCount({intTitle})

// JavaScript syntax
dvdObjRef.chapterCount({intTitle});

Description

DVD method; indicates the number of available chapters in a title.

Parameters

intTitle Optional. An integer that specifies the title that contains the chapters to count. If omitted, chapterCount() returns the number of available chapters in the current title.

See also

chapterCount, DVD
charPosToLoc()

Usage

-- Lingo syntax
memberObjRef.charPosToLoc(nthCharacter)

// JavaScript syntax
memberObjRef.charPosToLoc(nthCharacter);

Description

Field function; returns the point in the entire field cast member (not just the part that appears on the Stage) that is closest to a specified character. This is useful for determining the location of individual characters.

Values for charPosToLoc are in pixels from the top left corner of the field cast member. The nthCharacter parameter is 1 for the first character in the field, 2 for the second character, and so on.

Parameters

nthCharacter Required. The character to test.

Example

The following statement determines the point where the fiftieth character in the field cast member Headline appears and assigns the result to the variable location:

-- Lingo syntax
location = member("Headline").charPosToLoc(50)

// JavaScript syntax
var location = member("Headline").charPosToLoc(50);

chars()

Usage

chars(stringExpression, firstCharacter, lastCharacter)

Description

Function (Lingo only); identifies a substring of characters in an expression.

The expressions firstCharacter and lastCharacter must specify a position in the string.

If firstCharacter and lastCharacter are equal, then a single character is returned from the string. If lastCharacter is greater than the string length, only a substring up to the length of the string is identified. If lastCharacter is before firstCharacter, the function returns the value EMPTY.

To see an example of chars() used in a completed movie, see the Text movie in the Learning/Lingo folder inside the Director application folder.

In JavaScript syntax, use the String object’s substr() function.
Parameters

stringExpression Required. A string that specifies the expression from which a substring is returned.

firstCharacter Required. An integer that specifies the point at which the substring starts.

lastCharacter Required. An integer that specifies the point at which the substring ends.

Example

This statement identifies the sixth character in the word Macromedia:

put chars("Macromedia", 6, 6)  -- "m"

This statement identifies the sixth through tenth characters of the word Macromedia:

put chars("Macromedia", 6, 10)  -- "media"

The following statement tries to identify the sixth through twentieth characters of the word Macromedia. Because the word has only 10 characters, the result includes only the sixth through tenth characters.

put chars("Macromedia", 6, 20)  -- "media"

See also

char...of, length(), offset() (string function), number (characters)

charToNum()

Usage

(stringExpression).charToNum
charToNum(stringExpression)

Description

Function (Lingo only); returns the ASCII code that corresponds to the first character of an expression.

The charToNum() function is especially useful for testing the ASCII value of characters created by combining keys, such as the Control key and another alphanumeric key.

Director treats uppercase and lowercase letters the same if you compare them using the equal sign (=) operator; for example, the statement put ("M" = "m") returns the result 1 or TRUE.

Avoid problems by using charToNum() to return the ASCII code for a character and then use the ASCII code to refer to the character.

In JavaScript syntax, use the String object's charCodeAt() function.

Parameters

stringExpression Required. A string that specifies the expression to test.
Example

This statement displays the ASCII code for the letter A:

```
put ("A").charToNum
-- 65
```

The following comparison determines whether the letter entered is a capital A, and then navigates to either a correct sequence or incorrect sequence in the Score:

```
-- Lingo syntax
on CheckKeyHit theKey
    if (theKey).charToNum = 65 then
        go "Correct Answer"
    else
        go "Wrong Answer"
    end if
end
```

```
// JavaScript syntax
function CheckKeyHit(theKey) {
    if (theKey.charToNum() == 65) {
        go("Correct Answer");
    } else {
        go("Wrong Answer");
    }
}
```

See also

`numToChar()`

clearAsObjects()

Usage

```
-- Lingo syntax
clearAsObjects()
```

```
// JavaScript syntax
clearAsObjects();
```

Description

Command; resets the global Flash Player used for ActionScript objects and removes any ActionScript objects from memory. The command does not clear or reset references to those objects stored in Lingo. Lingo references will persist but will refer to nonexistent objects. You must set each reference to VOID individually.

The `clearAsObjects()` command affects only global objects, such as the array created in this statement:

```
-- Lingo syntax
myGlobalArray = newObject(#array)
```

```
// JavaScript syntax
myGlobalArray = new Array();
```

The `clearAsObjects()` command has no effect on objects created within sprite references, such as the following:

```
myArray = sprite(2).newObject(#array)
```
Parameters

None.

Example

This statement clears all globally created ActionScript objects from memory:

```
-- Lingo syntax
clearAsObjects()

// JavaScript syntax
clearAsObjects();
```

See also

newObject(), setCallback()

clearCache

Usage
clearCache

Description

Command; clears the Director network cache.

The `clearCache` command clears only the cache, which is separate from the browser's cache.

If a file is in use, it remains in the cache until it is no longer in use.

Parameters

None.

Example

This handler clears the cache when the movie starts:

```
-- Lingo syntax
on startMovie
  clearCache
end

// JavaScript syntax
function startMovie() {
  clearCache();
}
```

See also

cacheDocVerify(), cacheSize()
clearError()

Usage
-- Lingo syntax
memberObjRef.clearError()

// JavaScript syntax
memberObjRef.clearError();

Description
Flash command; resets the error state of a streaming Flash cast member to 0.
When an error occurs while a cast member is streaming into memory, Director sets the cast
member's state property to -1 to indicate that an error occurred. When this happens, you can
use the getError function to determine what type of error occurred and then use the
clearError command to reset the cast member's error state to 0. After you clear the member's
error state, Director tries to open the cast member if it is needed again in the Director movie.
Setting a cast member's pathName, linked, and preload properties also automatically clears the
error condition.

Parameters
None.

Example
This handler checks to see if an out-of-memory error occurred for a Flash cast member named
Dali, which was streaming into memory. If a memory error occurred, the script uses the
unloadCast command to try to free some memory; it then branches the playhead to a frame in
the Director movie named Artists, where the Flash movie sprite first appears, so Director can
again try to play the Flash movie. If something other than an out-of-memory error occurred, the
script goes to a frame named Sorry, which explains that the requested Flash movie can't be played.

-- Lingo syntax
on CheckFlashStatus
  if (member("Dali").getError() = #memory) then
    member("Dali").clearError()
    member("Dali").unload()
    unloadCast
  else
    _movie.go("Sorry")
  end if
end

// JavaScript syntax
function CheckFlashStatus() {
  var ge = member("Dali").getError();
  if (ge = "memory") |
    member("Dali").clearError();
    unloadCast;
    _movie.go("Artists");
  } else {
    _movie.go("Sorry");
  }
}

See also
state (Flash, SWA), getError() (Flash, SWA)
clearFrame()

Usage

-- Lingo syntax
_movie.clearFrame()

// JavaScript syntax
_movie.clearFrame();

Description
Movie method; clears all sprite channels in a frame during Score recording.

Parameters
None.

Example
The following handler clears the content of each frame before it edits that frame during Score generation:

-- Lingo syntax
on newScore
    _movie.beginRecording()
    repeat with counter = 1 to 50
        _movie.clearFrame()
        _movie.frameScript = 25
        _movie.updateFrame()
    end repeat
    _movie.endRecording()
end

// JavaScript syntax
function newScore() {
    _movie.beginRecording();
    for (var i = 1; i <= 50; i++) {
        _movie.clearFrame();
        _movie.frameScript = 25;
        _movie.updateFrame();
    }
    _movie.endRecording();
}

See also
beginRecording(). endRecording(). Movie. updateFrame()

clearGlobals()

Usage

-- Lingo syntax
_global.clearGlobals()

// JavaScript syntax
_global.clearGlobals();

Description
Global method; sets all global variables to VOID (Lingo) or null (JavaScript syntax).
This method is useful when initializing global variables or when opening a new movie that requires a new set of global variables.

Parameters

None.

Example

The following handlers set all global variables to VOID (Lingo) or null (JavaScript):

```--- Lingo syntax
on mouseDown
_performance.clearGlobals()
end

// JavaScript syntax
function mouseDown()
    _global.clearGlobals();
}```

See also

Global

clonable

Usage

- `member('whichCastmember').model('whichModel').clone('cloneName')`
- `member('whichCastmember').group('whichGroup').clone('cloneName')`
- `member('whichCastmember').light('whichLight').clone('cloneName')`
- `member('whichCastmember').camera('whichCamera').clone('cloneName')`

Description

3D command; creates a copy of the model, group, light, or camera and all of its children. The clone shares the parent of the model, group, light, or camera from which it was cloned.

A clone of a model uses the same model resource and is assigned the same shaderList as the original model.

If you do not specify the `cloneName`, or if you specify `''`, the clone will not be counted by the `count` method, but it will appear in the scene.

Parameters

- `cloneName` Required. Specifies the name of the new clone.

Example

This statement creates a clone named Teapot2 from the model named Teapot, and returns a reference to the new model.

```teapotCopy = member("3D World").model("Teapot").clone("Teapot2")```
**cloneDeep**

**Usage**

```plaintext
member(whichCastmember).model(whichModel).cloneDeep(cloneName)
member(whichCastmember).group(whichGroup).cloneDeep(cloneName)
member(whichCastmember).light(whichLight).cloneDeep(cloneName)
member(whichCastmember).camera(whichCamera).cloneDeep(cloneName)
```

**Description**

3D command; creates a copy of the model, group, light, or camera plus all of the following:
- The model resources, shaders, and textures used by the original model or group
- The children of the model, group, light, or camera
- The model resources, shaders, and textures used by the children

This method uses more memory and takes more time than the `clone` command.

**Parameters**

- `cloneName` Required. Specifies the name of the new clone.

**Example**

This statement creates a copy of the model named Teapot, its children, and the model resources, shaders, and textures used by Teapot and its children. The variable `teapotCopy` is a reference to the cloned model.

```plaintext
teapotCopy = member("3D World").model("Teapot").cloneDeep("Teapot2")
```

**See also**

`clone`, `cloneModelFromCastmember`, `cloneMotionFromCastmember`, `loadFile()`

**cloneModelFromCastmember**

**Usage**

```plaintext
member(whichCastmember).cloneModelFromCastmember\n(newModelName, sourceModelName, sourceCastmember)
```

**Description**

3D command; copies a model from a cast member, renames it, and inserts it into a cast member as a child of its 3D world.

This command also copies the children of `sourceModelName`, as well as the model resources, shaders, and textures used by the model and its children.

The source cast member must be finished loading for this command to work correctly.

**Parameters**

- `newModelName` Required. Specifies the name of the newly cloned model.
- `sourceModelName` Required. Specifies the model to clone.
- `sourceCastMember` Required. Specifies the cast member that contains the model to clone.
Example
This statement makes a copy of the model named Pluto of the cast member named Scene and
inserts it into the cast member named Scene2 with the new name Planet. The children of Pluto
are also imported, as are the model resources, shaders, and textures used by Pluto and its children.
member("Scene2").cloneModelFromCastmember("Planet", "Pluto", \
member("Scene"))

See also
cloneMotionFromCastmember, clone, cloneDeep, loadFile()

ccloneMotionFromCastmember

Usage
member(whichCastmember).cloneMotionFromCastmember(newMotionName, \nsourceMotionName, sourceCastmember)

Description
3D command; copies a motion from a cast member, renames it, and inserts it into a cast member.
The source cast member must be finished loading for this command to work correctly.

Parameters
newMotionName Required. Specifies the name of the newly cloned motion.
sourceMotionName Required. Specifies the motion to clone.
sourceCastMember Required. Specifies the cast member that contains the motion to clone.

Example
This statement copies the motion named Walk from the cast member named ParkScene, names
the copy FunnyWalk, and puts the copy in the cast member gbMember.
member("gbMember").cloneMotionFromCastmember("FunnyWalk", \n"Walk", member("ParkScene"))

See also
map (3D), cloneModelFromCastmember, clone, cloneDeep, loadFile()

close()

Usage
.-- Lingo syntax
windowObjRef.close()

// JavaScript syntax
windowObjRef.close();

Description
Window method; closes a window.
Closing a window that is already closed has no effect.
Be aware that closing a window does not stop the movie in the window nor clear it from memory. This method simply closes the window in which the movie is playing. You can reopen it quickly by using the `open()` (Window) method. This allows rapid access to windows that you want to keep available.

If you want to completely dispose of a window and clear it from memory, use the `forget()` method. Make sure that nothing refers to the movie in that window if you use the `forget()` method, or you will generate errors when scripts try to communicate or interact with the forgotten window.

**Parameters**

None.

**Example**

This statement closes the window named Panel, which is in the subfolder MIAW Sources within the current movie’s folder:

```-- Lingo syntax
window(_movie.path & "MIAW Sources\Panel").close()
```

```// JavaScript syntax
window(_movie.path + "MIAW Sources\Panel").close();
```

This statement closes the window that is number 5 in `windowList`:

```-- Lingo syntax
window(5).close()
```

```// JavaScript syntax
window(5).close();
```

**See also**

`forget()` (Window), `open()` (Window), Window

### closeFile()

**Usage**

```-- Lingo syntax
fileioObjRef.closeFile()
```

```// JavaScript syntax
fileioObjRef.closeFile();
```

**Description**

Fileio method; Closes a file.

**Parameters**

None.

**See also**

Fileio
closeXlib

Usage

closeXlib whichFile

Description

Command; closes an Xlibrary file.

Xtra extensions are stored in Xlibrary files. Xlibrary files are resource files that contain Xtra extensions. HyperCard XCMDs and XFCNs can also be stored in Xlibrary files.

The closeXlib command doesn't work for URLs.

In Windows, using the DLL extension for Xtra extensions is optional.

It is good practice to close any file you have opened as soon as you have finished using it.

Note: This command is not supported in Shockwave Player.

Parameters

whichFile Optional. Specifies the Xlibrary file to close. If whichFile is in a folder other than that for the current movie, whichFile must specify a pathname. If whichFile is omitted, all open Xlibraries are closed.

Example

This statement closes all open Xlibrary files:

closeXlib

This statement closes the Xlibrary Video Disc Xlibrary when it is in the same folder as the movie:

closeXlib "Video Disc Xlibrary"

The following statement closes the Xlibrary Transporter Xtra extensions in the folder New Xtras, which is in the same folder as the movie. The disk is identified by the variable currentDrive:

closeXlib "@:New Xtras:Transporter Xtras"

See also

text( ), openXlib

color()

Usage

-- Lingo syntax
color(intPaletteIndex)
color(intRed, intGreen, intBlue)

// JavaScript syntax
color(intPaletteIndex);
color(intRed, intGreen, intBlue);

Description

Top level function and data type. Returns a Color data object using either RGB or 8-bit palette index values.

The resulting color object can be applied to cast members, sprites, and the Stage where appropriate.
Parameters

*intPaletteIndex* Required if using 8-bit palette values. An integer that specifies the 8-bit palette value to use. Valid values range from 0 to 255. All other values are truncated.

*intRed* Required if using RGB values. An integer that specifies the red color component in the current palette. Valid values range from 0 to 255. All other values are truncated.

*intGreen* Required if using RGB values. An integer that specifies the green color component in the current palette. Valid values range from 0 to 255. All other values are truncated.

*intBlue* Required if using RGB values. An integer that specifies the blue color component in the current palette. Valid values range from 0 to 255. All other values are truncated.

Example

These statements display the color of sprite 6 in the Message window, and then set the color of sprite 6 to a new value:

-- Lingo syntax
put(sprite(6).color) -- paletteIndex(255)
sprite(6).color = color(137)
put(sprite(6).color) -- paletteIndex(137)

// JavaScript syntax
put(sprite(6).color) // paletteIndex(255);
sprite(6).color = color(137);
put(sprite(6).color) // paletteIndex(137);

constrainH()

Usage

-- Lingo syntax
_movie.constrainH(intSpriteNum, intPosn)

// JavaScript syntax
_movie.constrainH(intSpriteNum, intPosn);

Description

Movie method; returns an integer whose value depends on the horizontal coordinates of the left and right sides of a sprite.

The returned integer can be one of three possible values.

- If the *intPosn* parameter is between the values of the sprite's left and right coordinates, the returned integer equals *intPosn*.
- If the *intPosn* parameter is less than the value of the sprite's left coordinate, the returned integer changes to the value of the sprite's left coordinate.
- If the *intPosn* parameter is greater than the value of the sprite's right coordinate, the returned integer changes to the value of the sprite's right coordinate.

This method does not change the sprite's properties.

Both the `constrainH()` and `constrainV()` methods constrain only one axis each.
Parameters

`intSpriteNum` Required. An integer that specifies the sprite whose horizontal coordinates are evaluated against `intPosn`.

`intPosn` Required. An integer to be evaluated against by the horizontal coordinates of the left and right sides of the sprite identified by `intSpriteNum`.

Example

These statements check the `constrainH` function for sprite 1 when it has left and right coordinates of 40 and 60:

-- Lingo syntax
put(constrainH(1, 20)) -- 40
put(constrainH(1, 55)) -- 55
put(constrainH(1, 100)) -- 60

// JavaScript syntax
put(constrainH(1, 20)); // 40
put(constrainH(1, 55)); // 55
put(constrainH(1, 100)); // 60

This statement constrains a moveable slider (sprite 1) to the edges of a gauge (sprite 2) when the mouse pointer goes past the edge of the gauge:

-- Lingo syntax
sprite(1).locH = _movie.constrainH(2, _mouse.mouseH)

// JavaScript syntax
sprite(1).locH = _movie.constrainH(2, _mouse.mouseH);

See also

`constrainV()`. Movie

`constrainV()`

Usage

-- Lingo syntax
_movie.constrainV(intSpriteNum, intPosn)

// JavaScript syntax
_movie.constrainV(intSpriteNum, intPosn);

Description

Movie method; returns an integer whose value depends on the vertical coordinates of the top and bottom sides of a sprite.

The returned integer can be one of three possible values.

- If the `intPosn` parameter is between the values of the sprite’s top and bottom coordinates, the returned integer equals `intPosn`.
- If the `intPosn` parameter is less than the value of the sprite’s top coordinate, the returned integer changes to the value of the sprite’s top coordinate.
- If the `intPosn` parameter is greater than the value of the sprite’s bottom coordinate, the returned integer changes to the value of the sprite’s bottom coordinate.

This method does not change the sprite’s properties.
Both the `constrainV()` and `constrainH()`s constrain only one axis each.

**Parameters**

- `intSpriteNum` Required. An integer that identifies the sprite whose vertical coordinates are evaluated against `intPosn`.
- `intPosn` Required. An integer to be evaluated against by the vertical coordinates of the left and right sides of the sprite identified by `intSpriteNum`.

**Example**

These statements check the `constrainV` function for sprite 1 when it has top and bottom coordinates of 40 and 60:

---

**Lingo syntax**

```plaintext
put(constrainV(1, 20)) -- 40
put(constrainV(1, 55)) -- 55
put(constrainV(1, 100)) -- 60
```

**JavaScript syntax**

```plaintext
put(constrainV(1, 20)); // 40
put(constrainV(1, 55)); // 55
put(constrainV(1, 100)); // 60
```

This statement constrains a moveable slider (sprite 1) to the edges of a gauge (sprite 2) when the mouse pointer moves past the edge of the gauge:

---

**Lingo syntax**

```plaintext
sprite(1).locV = _movie.constrainV(2, _mouse.mouseH)
```

**JavaScript syntax**

```plaintext
sprite(1).locV = _movie.constrainV(2, _mouse.mouseH);
```

See also

- `constrainH()`
- `Movie`

**copyPixels()**

**Usage**

---

**Lingo syntax**

```plaintext
imageObjRef.copyPixels(sourceImgObj, destRectOrQuad, sourceRect {, paramList})
```

**JavaScript syntax**

```plaintext
imageObjRef.copyPixels(sourceImgObj, destRectOrQuad, sourceRect {, paramList});
```

**Description**

Image method. Copies the contents of a rectangle in an existing image object into a new image object.

When copying pixels from one area of a cast member to another area of the same member, it is best to copy the pixels first into a duplicate image object before copying them back into the original member. Copying directly from one area to another in the same image is not recommended.

To simulate matte ink with `copyPixels()`, create a matte object with `createMatte()` and then pass that object as the `#maskImage` parameter of `copyPixels()`.
To see an example of quad used in a completed movie, see the Quad movie in the Learning/Lingo folder inside the Director application folder.

**Parameters**

- **sourceImgObj** Required. A reference to the source image object from which pixels are copied.
- **destRectOrQuad** Required if copying pixels into a screen coordinate rectangle or a floating point quad. The rectangle or quad into which pixels are copied.
- **sourceRect** Required. The source rectangle from which pixels are copied.
- **paramList** Optional. A parameter list that can be used to manipulate the copied pixels before they are placed into `destRect` or `destQuad`. The property list may contain any or all of the following parameters.

<table>
<thead>
<tr>
<th>Property</th>
<th>Use and Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>#color</td>
<td>The foreground color to apply for colorization effects. The default color is black.</td>
</tr>
<tr>
<td>#bgColor</td>
<td>The background color to apply for colorization effects or background transparency. The default color is white.</td>
</tr>
<tr>
<td>#ink</td>
<td>The type of ink to apply to the copied pixels. This can be an ink symbol or the corresponding numeric ink value. The default ink is #copy.</td>
</tr>
<tr>
<td>#blendLevel</td>
<td>The degree of blend (transparency) to apply to the copied pixels. The range of values is from 0 to 255. The default value is 255 (opaque). Using a value less than 255 forces the #ink setting to be #blend, or #blendTransparent if it was originally #backgroundTransparent. #blendLevel could also be replaced with #blend; if so, use a value range of 0 to 100.</td>
</tr>
<tr>
<td>#dither</td>
<td>A TRUE or FALSE value that determines whether the copied pixels will be dithered when placed into the destRect in 8- and 16-bit images. The default value is FALSE, which maps the copied pixels directly into the imageObjRef's color palette.</td>
</tr>
<tr>
<td>#useFastQuads</td>
<td>A TRUE or FALSE value that determines whether quad calculations are made using the faster but less precise method available in Director when copying pixels into destQuad. Set to TRUE to use quads for simple rotation and skew operations. Set to FALSE for arbitrary quads, such as those used for perspective transformations. The default value is FALSE.</td>
</tr>
<tr>
<td>#maskImage</td>
<td>Specifies a mask or matte object, created with the createMask() or createMatte()s, that will be used as a mask for the pixels being copied. This enables the effects of mask and matte sprite inks to be duplicated. If the source image has an alpha channel and its useAlpha property is TRUE, the alpha channel is used and the specified mask or matte is ignored. The default is no mask.</td>
</tr>
<tr>
<td>#maskOffset</td>
<td>A point indicating the amount of x and y offset to apply to the mask specified by #maskImage. The offset is relative to the upper left corner of the source image. The default offset is (0, 0).</td>
</tr>
</tbody>
</table>

**Example**

This statement copies the entire image of member Happy into the rectangle of member flower. If the members are different sizes, the image of member Happy will be resized to fit the rectangle of member flower.
The following statement copies part of the image of member Happy into part of member flower. The part of the image copied from Happy is within rectangle(0, 0, 200, 90). It is pasted into rectangle(20, 20, 100, 40) within the image of member flower. The copied portion of Happy is resized to fit the rectangle into which it is pasted.

The following statement copies the entire image of member Happy into a rectangle within the image of member flower. The rectangle into which the copied image of member Happy is pasted is the same size as the rectangle of member Happy, so the copied image is not resized. The blend level of the copied image is 50, so it is semi-transparent, revealing the part of member flower it is pasted over.

See also

 color(), image()

**copyToClipBoard()**

**Usage**

-- Lingo syntax
memberObjRef.copyToClipBoard()

// JavaScript syntax
memberObjRef.copyToClipBoard();

**Description**

Member method; copies a specified cast member to the Clipboard.

Calling this method does not require the Cast window to be active. This method is useful when copying cast members between movies or applications.

**Parameters**

None.

**Example**

This statement copies the cast member named chair to the Clipboard:

-- Lingo syntax
member("chair").copyToClipBoard()

// JavaScript syntax
member("chair").copyToClipBoard();

This statement copies cast member number 5 to the Clipboard:

-- Lingo syntax
member(5).copyToClipBoard()

// JavaScript syntax
member(5).copyToClipBoard();

See also

Member, pasteClipBoardInto()
cos()

Usage
   (angle).cos
   cos (angle)

Description
   Function (Lingo only); calculates the cosine of the specified angle, which must be expressed
   in radians.
   
   In JavaScript syntax, use the Math object’s cos() function.

Parameters
   angle Required. An integer that specifies the angle to test.

Example
   The following statement calculates the cosine of PI divided by 2 and displays it in the
   Message window:
   put (PI/2).cos

See also
   atan(), PI, sin()

count()

Usage
   -- Lingo syntax
   list.count
   object.count

   // JavaScript syntax
   list.count;
   object.count;

Description
   Function; returns the number of entries in a linear or property list, the number of properties in a
   parent script without counting the properties in an ancestor script, or the chunks of a text
   expression such as characters, lines, or words.

   The count command works with linear and property lists, objects created with parent scripts, and
   the globals property.

   To see an example of count() used in a completed movie, see the Text movie in the Learning/
   Lingo folder inside the Director application folder.

Parameters
   None.
Example

This statement displays the number 3, the number of entries:

```lingo
put([10,20,30].count) -- 3
```
```
// JavaScript syntax
put(list(10,20,30).count); // 3
```

See also
globals

createFile()

Usage

```lingo
fileioObjRef.createFile(stringFileName)
```
```
// JavaScript syntax
fileioObjRef.createFile(stringFileName);
```

Description

Fileio method; Creates a specified file.

Parameters

- `stringFileName` Required. A string that specifies the path and name of the file to create.

See also

Fileio

createMask()

Usage

`imageObject.createMask()`

Description

This function creates and returns a mask object for use with the copyPixels() function.

Mask objects aren’t image objects; they're useful only with the copyPixels() function for duplicating the effect of mask sprite ink. To save time, if you plan to use the same image as a mask more than once, it's best to create the mask object and save it in a variable for reuse.

Example

This statement copies the entire image of member Happy into a rectangle within the image of member brown square. Member gradient2 is used as a mask with the copied image. The mask is offset by 10 pixels up and to the left of the rectangle into which the image of member Happy is pasted.

```lingo
member("brown square").image.copyPixels(member("Happy").image, rect(20, 20, 150, 108), member("Happy").rect, [#maskImage:member("gradient2").image.createMask(), maskOffset:point(-10, -10)])
```

See also

copyPixels(), createMatte(), ink
createMatte()

Syntax

```
imageObject.createMatte({alphaThreshold})
```

Description

This function creates and returns a matte object that you can use with `copyPixels()` to duplicate the effect of the matte sprite ink. The matte object is created from the specified image object's alpha layer. The optional parameter `alphaThreshold` excludes from the matte all pixels whose alpha channel value is below that threshold. It is used only with 32-bit images that have an alpha channel. The `alphaThreshold` must be a value between 0 and 255.

Matte objects aren't image objects; they are useful only with the `copyPixels()` function. To save time, if you plan to use the same image as a matte more than once, it's best to create the matte and save it in a variable for reuse.

Example

This statement creates a new matte object from the alpha layer of the image object `testImage` and ignores pixels with alpha values below 50%:

```
newMatte = testImage.createMatte(128)
```

See also

`copyPixels()`, `createMask()`

crop() (Image)

Usage

```
-- Lingo syntax
imageObjRef.crop(rectToCropTo)

// JavaScript syntax
imageObjRef.crop(rectToCropTo);
```

Description

Image method. Returns a new image object that contains a copy of a source image object, cropped to a given rectangle.

Calling `crop()` does not alter the source image object.

The new image object does not belong to any cast member and has no association with the Stage. To assign the new image to a cast member, set the `image` property of that cast member.

Parameters

`rectToCropTo` Required. The rectangle to which the new image is cropped.

Example

This Lingo takes a snapshot of the Stage and crops it to the `rect` of sprite 10, capturing the current appearance of that sprite on the Stage:

This statement uses the rectangle of cast member Happy to crop the image of cast member Flower, then sets the image of cast member Happy to the result:

```
member("Happy").image = member("Flower").image.crop(member("Happy").rect)
```
See also
   image (Image), image(), rect (Image)

crop() (Bitmap)

Usage
   -- Lingo syntax
   memberObjRef.crop()

   // JavaScript syntax
   memberObjRef.crop();

Description
   Bitmap command; allows a bitmap cast member to be cropped to a specific size.
   You can use crop to trim existing cast members, or in conjunction with the picture of the Stage to
   grab a snapshot and then crop it to size for display.
   The registration point is kept in the same location so the bitmap does not move in relation to the
   original position.

Parameters
   rectToCropTo Required. Specifies the rectangle to which a cast member is cropped.

Example
   This statement sets an existing bitmap member to a snapshot of the Stage, then crops the
   resulting image to a rectangle equal to sprite 10:
     --- Lingo syntax
     stageImage = (_movie.stage).image
     spriteImage = stageImage.crop(sprite(10).rect)
     member("sprite snapshot").image = spriteImage
     
     // JavaScript syntax
     var stageImage = (_movie.stage).image;
     var spriteImage = stageImage.crop(sprite(10).rect);
     member("sprite snapshot").image = spriteImage;

See also
   picture (Member)

cross

Usage
   vector1.cross(vector2)

Description
   3D vector method; returns a vector which is perpendicular to both vector1 and vector2.

Example
   In this example, pos1 is a vector on the x axis and pos2 is a vector on the y axis. The value
   returned by pos1.cross(pos2) is vector( 0.0000, 0.0000, 1.00000e4 ), which is
   perpendicular to both pos1 and pos2.
pos1 = vector(100, 0, 0)
pos2 = vector(0, 100, 0)
put pos1.cross(pos2)
-- vector( 0.0000, 0.0000, 1.00000e4 )

See also
crossProduct(), perpendicularTo

crossProduct()

Usage
vector1.crossProduct(vector2)

Description
3D vector method; returns a vector which is perpendicular to both vector1 and vector2.

Example
In this example, pos1 is a vector on the x axis and pos2 is a vector on the y axis. The value returned by
pos1.crossProduct(pos2) is vector( 0.0000, 0.0000, 1.00000e4 ), which is perpendicular to both pos1 and pos2.

pos1 = vector(100, 0, 0)
pos2 = vector(0, 100, 0)
put pos1.crossProduct(pos2)
-- vector( 0.0000, 0.0000, 1.00000e4 )

See also
perpendicularTo, cross
cursor()

Usage
-- Lingo syntax
_player.cursor(intCursorNum)
_player.cursor(cursorMemNum, maskMemNum)
_player.cursor(cursorMemRef)

// JavaScript syntax
_player.cursor(intCursorNum);
_player.cursor(cursorMemNum, maskMemNum);
_player.cursor(cursorMemRef);

Description
Player method; changes the cast member or built-in cursor that is used for a cursor and stays in
effect until you turn it off by setting the cursor to 0.

• Use the syntax _player.cursor(cursorMemNum, maskMemNum) to specify the number of a
cast member to use as a cursor and its optional mask. The cursor's hot spot is the registration
point of the cast member.

The cast member that you specify must be a 1-bit cast member. If the cast member is larger
than 16 by 16 pixels, Director crops it to a 16-by-16-pixel square, starting in the upper left
corner of the image. The cursor's hot spot is still the registration point of the cast member.
- Use the syntax `cursor(cursorMemRef)` for the custom cursors available through the Cursor Xtra.

**Note:** Although the Cursor Xtra allows cursors of different cast library types, text cast members cannot be used as cursors.

- Use the syntax `cursor(intCursorNum)` to specify default system cursors. The term `intCursorNum` must be one of the following integer values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1,0</td>
<td>Arrow</td>
</tr>
<tr>
<td>1</td>
<td>I-Beam</td>

</tr>
</tbody>
</table>

During system events such as file loading, the operating system may display the watch cursor and then change to the pointer cursor when returning control to the application, overriding the cursor command settings from the previous movie. To use `cursor()` at the beginning of any new movie that is loaded in a presentation using a custom cursor for multiple movies, store any special cursor resource number as a global variable that remains in memory between movies.
Cursor commands can be interrupted by an Xtra or other external agent. If the cursor is set to a value in Director and an Xtra or external agent takes control of the cursor, resetting the cursor to the original value has no effect because Director doesn't perceive that the cursor has changed. To work around this, explicitly set the cursor to a third value and then reset it to the original value.

**Parameters**

- `intCursorNum` Required when using an integer to identify a cursor. An integer that specifies the built-in cursor to use as a cursor.
- `cursorMemNum` Required when using a cast member number and its optional mask to identify the cursor. An integer that specifies the cast member number to use as a cursor.
- `maskMemNum` Required when using a cast member number and its optional mask to identify the cursor. An integer that specifies the mask number of `cursorMemNum`.
- `cursorMemRef` Required when using a cast member reference to identify the cursor. A reference to the cast member to use as a cursor.

**Example**

This statement changes the cursor to a watch cursor on the Macintosh, and hourglass in Windows, whenever the value in the variable named `status` equals 1:

```lingo
if (status = 1) then
  _player.cursor(4)
end if
```

```javascript
if (status == 1) {
  _player.cursor(4);
}
```

This handler checks whether the cast member assigned to the variable is a 1-bit cast member and then uses it as the cursor if it is:

```lingo
on myCursor(someMember)
  if (member(someMember).depth = 1) then
    _player.cursor(someMember)
  else
    _sound.beep()
  end if
end
```

```javascript
function myCursor(someMember) {
  if (member(someMember).depth == 1) {
    _player.cursor(someMember);
  } else {
    _sound.beep();
  }
}
```

**See also**

`Player`
date() (formats)

Usage

-- Lingo syntax syntax
date({stringFormat})
date({intFormat})
date({intYearFormat, intMonthFormat, intDayFormat})

// JavaScript syntax
Date(“month dd, yyyy hh:mm:ss”);
Date(“month dd, yyyy”);
Date(yy, mm, dd, hh, mm, ss);
Date(yy, mm, dd);
Date(milliseconds);

Description

Top level function and data type. Creates a standard, formatted date object instance for use with other date object instances in arithmetic operations and for use in manipulating dates across platforms and in international formats.

Lingo date objects and JavaScript syntax date objects are different; therefore, Lingo date objects cannot be created using JavaScript syntax, and JavaScript syntax date objects cannot be created using Lingo syntax.

Create a new JavaScript syntax Date object using the new Date() syntax. Case is important in JavaScript syntax. For example, using new date() results in a runtime error.

When creating a date using Lingo, use four digits for the year, two digits for the month, and two digits for the day. The following expressions all return a date object equivalent to October 21, 2004.

<table>
<thead>
<tr>
<th>Date Format</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>date(“20041021”)</td>
</tr>
<tr>
<td>integer</td>
<td>date(20041021)</td>
</tr>
<tr>
<td>comma separated</td>
<td>date(2004, 10, 21)</td>
</tr>
</tbody>
</table>

The individual properties of the returned date object are as follows.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#year</td>
<td>An integer representing the year</td>
</tr>
<tr>
<td>#month</td>
<td>An integer representing the month of the year</td>
</tr>
<tr>
<td>#day</td>
<td>An integer representing the day of the month</td>
</tr>
</tbody>
</table>

Addition and subtraction operations on the date are interpreted as the addition and subtraction of days.

Parameters

stringFormat Optional when creating a Lingo date object. A string that specifies the new date object.
**intFormat** Optional when creating a Lingo date object. An integer that specifies the new date object.

**intYearFormat** Optional when creating a Lingo date object. An integer that specifies the four-digit year of the new date object.

**intMonthFormat** Optional when creating a Lingo date object. An integer that specifies the two-digit month of the new date object.

**intDayFormat** Optional when creating a Lingo date object. An integer that specifies the two-digit day of the new date object.

**month** Optional when creating an JavaScript syntax Date object. A string that specifies the month of the new Date object. Valid values range from 0 (January) to 11 (December).

**dd** Optional when creating an JavaScript syntax Date object. A two-digit integer that specifies the day of the new Date object. Valid values range from 0 (Sunday) to 6 (Saturday).

**yyyy** Optional when creating an JavaScript syntax Date object. A four-digit integer that specifies the year of the new Date object.

**hh** Optional when creating an JavaScript syntax Date object. A two-digit integer that specifies the hour of the new Date object. Valid values range from 0 (12:00am) to 23 (11:00pm).

**mm** Optional when creating an JavaScript syntax Date object. A two-digit integer that specifies the minute of the new Date object. Valid values range from 0 to 59.

**ss** Optional when creating an JavaScript syntax Date object. A two-digit integer that specifies the seconds of the new Date object. Valid values range from 0 to 59.

**yy** Optional when creating an JavaScript syntax Date object. A two-digit integer that specifies the year of the new Date object. Valid values range from 0 to 99.

**milliseconds** Optional when creating an JavaScript syntax Date object. An integer that specifies the milliseconds of the new Date object. Valid values range from 0 to 999.

**Example**

These statements create and determine the number of days between two dates:

-- Lingo syntax syntax
myBirthday = date(19650712)
myBirthday = date(19450529)
put("There are " && abs(yourBirthday - myBirthday) && " days between our \birthdays."")

// JavaScript syntax
var myBirthday = new Date(1965, 07, 12);
var yourBirthday = new Date(1945, 05, 29);
put("There are " + Math.abs(((yourBirthday - myBirthday)/1000/60/60/24)) + " days between our birthdays.");

These statements access an individual property of a date:

-- Lingo syntax syntax
myBirthday = date(19650712)
put("I was born in month number " && myBirthday.month)

// JavaScript syntax
var myBirthday = new Date(1965, 07, 12);
put("I was born in month number " + myBirthday.getMonth());
**date() (System)**

**Usage**

-- Lingo syntax
_system.date({yyyymmdd})

// JavaScript syntax
_system.date({yyyymmdd});

**Description**

System method; returns the current date in the system clock.

The format Director uses for the date varies, depending on how the date is formatted on the computer.

- In Windows, you can customize the date display by using the International control panel. (Windows stores the current short date format in the System.ini file. Use this value to determine what the parts of the short date indicate.)
- On the Macintosh, you can customize the date display by using the Date and Time control panel.

**Parameters**

*yyyymmdd* Optional. A number that specifies the four-digit year (*yyyy*), two-digit month (*mm*), and two-digit day (*dd*) of the returned date.

**Example**

This statement tests whether the current date is January 1 by checking whether the first four characters of the date are 1/1. If it is January 1, the alert “Happy New Year!” appears:

-- Lingo syntax
if (_system.date().char[1..4] = "1/1") then
    _player.alert("Happy New Year!")
end if

// JavaScript syntax
if (_system.date().toString().substr(0, 4) == "1/1") {
    _player.alert("Happy New Year!");
}

**See also**

System

delay()

**Usage**

-- Lingo syntax
_movie.delay(intTicks)

// JavaScript syntax
_movie.delay(intTicks);

**Description**

Movie method; pauses the playhead for a given amount of time.
The only mouse and keyboard activity possible during this time is stopping the movie by pressing Control+Alt+period (Windows) or Command+period (Macintosh). Because it increases the time of individual frames, \texttt{delay()} is useful for controlling the playback rate of a sequence of frames.

The \texttt{delay()} method can be applied only when the playhead is moving. However, when \texttt{delay()} is in effect, handlers still run; only the playhead halts, not script execution. Place scripts that use \texttt{delay()} in either an \texttt{enterFrame} or \texttt{exitFrame} handler.

To mimic the behavior of a halt in a handler when the playhead is not moving, use the \texttt{milliseconds} property of the \texttt{System} object and wait for the specified amount of time to pass before exiting the frame.

**Parameters**

\texttt{intTicks} Required. An integer that specifies the number of ticks to pause the playhead. Each tick is 1/60 of a second.

**Example**

This handler delays the movie for 2 seconds when the playhead exits the current frame:

\begin{verbatim}
-- Lingo syntax
on keyDown
    _movie.delay(2*60)
end

// JavaScript syntax
function keyDown()
{
    _movie.delay(2*60);
}
\end{verbatim}

This handler, which can be placed in a frame script, delays the movie a random number of ticks:

\begin{verbatim}
-- Lingo syntax
on keyDown
    if (_key.key = "x") then
        _movie.delay(random(180))
    end if
end

// JavaScript syntax
function keyDown()
{
    if (_key.key == "x") {
        _movie.delay(random(180));
    }
}
\end{verbatim}

**See also**

\texttt{endFrame, milliseconds, Movie}
delete()

Usage

-- Lingo syntax
fileioObjRef.delete()

// JavaScript syntax
fileioObjRef.delete();

Description
Fileio method; Deletes a file.

Parameters
None.

See also
Fileio

deleteAt

Usage

list.deleteAt(number)

Description
List command; deletes an from a linear or property list.

The deleteAt command checks whether an item is in a list; if you try to delete an object that isn’t in the list, Director displays an alert.

Parameters

number Required. Specifies the position of the item in the list to delete.

Example

This statement deletes the second item from the list named designers, which contains [gee, kayne, ohashi]:

designers = [*gee*, “kayne”, “ohashi”]
designers.deleteAt(2)

The result is the list [gee, ohashi].

This handler checks whether an object is in a list before attempting to delete it:

on myDeleteAt theList, theIndex
  if theList.count < theIndex then
    beep
  else
    theList.deleteAt(theIndex)
  end if
end

See also
addAt
deleteCamera

Usage

member(whichCastmember).deleteCamera(cameraName)
member(whichCastmember).deleteCamera(index)
sprite(whichSprite).deleteCamera(cameraOrIndex)

Description

3D command; in a cast member, this command removes the camera from the cast member and
the 3D world. Children of the camera are removed from the 3D world but not deleted.

It is not possible to delete the default camera of the cast member.

In a sprite, this command removes the camera from the sprite's list of cameras. The camera is not
deleted from the cast member.

Parameters

cameraNameOrNum Required. A string or an integer that specifies the name or index position of
the camera to delete.

Example

This statement deletes two cameras from the cast member named Room: first the camera named
Camera06, and then camera 1.

member("Room").deleteCamera("Camera06")
member("Room").deleteCamera(1)

This statement removes two cameras from the list of cameras for sprite 5: first the second camera
in the list, then the camera named Camera06

sprite(5).deleteCamera(2)
sprite(5).deleteCamera(member("Room").camera("Camera06")))

See also

newCamera, addCamera, cameraCount()

deleteFrame()

Usage

-- Lingo syntax
_movie.deleteFrame()

// JavaScript syntax
_movie.deleteFrame();

Description

Movie method; deletes the current frame and makes the next frame the new current frame during
a Score generation session only.

Parameters

None.
Example

The following handler checks whether the sprite in channel 10 of the current frame has gone past the right edge of a 640-by-480-pixel Stage and deletes the frame if it has:

```
-- Lingo syntax
on testSprite
    _movie.beginRecording()
    if (sprite(10).locH > 640) then
        _movie.deleteFrame()
    end if
    _movie.endRecording()
end
```

```javascript
function testSprite()
    _movie.beginRecording();
    if (sprite(10).locH > 640) {
        _movie.deleteFrame();
    }
    _movie.endRecording();
}
```

See also

`beginRecording()`, `endRecording()`, `Movie`, `updateFrame()`

deleteGroup

Usage

```lingo
member(whichCastmember).deleteGroup(whichGroup)
member(whichCastmember).deleteGroup(index)
```

Description

3D command; removes the group from the cast member and the 3D world. Children of the group are removed from the 3D world but not deleted.

It is not possible to delete the group named World, which is the default group.

Parameters

- `groupNameOrNum` Required. A string or integer that specifies the name or index position of the group to delete.

Example

The first line of this example deletes the group Dummy16 from the cast member Scene. The second line deletes the third group of Scene.

```
member("Scene").deleteGroup("Dummy16")
member("Scene").deleteGroup(3)
```

See also

`newGroup`, `child (3D)`, `parent`
**deleteLight**

**Usage**
```
member(whichCastmember).deleteLight(whichLight)
member(whichCastmember).deleteLight(index)
```

**Description**
3D command; removes the light from the cast member and the 3D world. Children of the light are removed from the 3D world but not deleted.

**Parameters**
`lightNameOrNum` Required. A string or integer that specifies the name or index position of the light to delete.

**Example**
These examples delete lights from the cast member named Room.
```
member("Room").deleteLight("ambientRoomLight")
member("Room").deleteLight(6)
```

**See also**
`newLight`

**deleteModel**

**Usage**
```
member(whichCastmember).deleteModel(whichModel)
member(whichCastmember).deleteModel(index)
```

**Description**
3D command; removes the model from the cast member and the 3D world. Children of the model are removed from the 3D world but not deleted.

**Parameters**
`modelNameOrNum` Required. A string or integer that specifies the name or index position of the model to delete.

**Example**
The first line of this example deletes the model named Player3 from the cast member named gbWorld. The second line deletes the ninth model of gbWorld.
```
member("gbWorld").deleteModel("Player3")
member("gbWorld").deleteModel(9)
```

**See also**
`newModel`
deleteModelResource

Usage
member(whichCastmember).deleteModelResource(whichModelResource)
member(whichCastmember).deleteModelResource(index)

Description
3D command; removes the model resource from the cast member and the 3D world.
Models using the deleted model resource become invisible, because they lose their geometry, but
they are not deleted or removed from the world.

Parameters
resourceNameOrNum Required. A string or integer that specifies the name or index position of
the model resource to delete.

Example
These examples delete two model resources from the cast member named StreetScene.
member("StreetScene").deleteModelResource("HouseB")
member("StreetScene").deleteModelResource(3)

See also
newModelResource, newMesh

deleteMotion

Usage
member(whichCastmember).deleteMotion(whichMotion)
member(whichCastmember).deleteMotion(index)

Description
3D command; removes the motion from the cast member.

Parameters
motionNameOrNum Required. A string or integer that specifies the name or index position of the
motion to delete.

Example
The first line of this example deletes the motion named BackFlip from the cast member named
PicnicScene. The second line deletes the fifth motion in PicnicScene.
member("PicnicScene").deleteMotion("BackFlip")
member("PicnicScene").deleteMotion(5)

See also
newMotion(), removeLast()
deleteOne

Usage

list.deleteOne(value)
deleOne list, value

Description

List command; deletes a value from a linear or property list. For a property list, deleteOne also
deletes the property associated with the deleted value. If the value appears in the list more than
once, deleteOne deletes only the first occurrence.

Attempting to delete a property has no effect.

Parameters

value Required. The value to delete from the list.

Example

The first statement creates a list consisting of the days Tuesday, Wednesday, and Friday. The
second statement deletes the name Wednesday from the list.

days = ["Tuesday", "Wednesday", "Friday"]
days.deleteOne("Wednesday")
put days

The put days statement causes the Message window to display the result:
-- ["Tuesday", "Friday"].

deleteProp

Usage

list.deleteProp(item)
deleProp list, item

Description

List command; deletes the specified item from the specified list.

- For linear lists, replace item with the number identifying the list position of the item to be
deleted. The deleteProp command for linear lists is the same as the deleteAt command. If
the number is greater than the number of items in the list, a script error occurs.
- For property lists, replace item with the name of the property to be deleted. Deleting a
property also deletes its associated value. If the list has more than one of the same property,
only the first property in the list is deleted.

Parameters

item Required. The item to delete from the list.

Example

This statement deletes the color property from the list [#height:100, #width: 200, #color: 34,
#ink: 15], which is called spriteAttributes:
spriteAttributes.deleteProp(#color)
The result is the list [#height:100, #width: 200, #ink: 15].
See also
deleteAt
deleteShader

Usage

member(whichCastmember).deleteShader(whichShader)
member(whichCastmember).deleteShader(index)

Description

3D command; removes the shader from the cast member.

Parameters

shaderNameOrNum Required. A string or integer that specifies the name or index position of the shader to delete.

Example

The first line of this example deletes the shader Road from the cast member named StreetScene.
The second line deletes the third shader of StreetScene.

member("StreetScene").deleteShader("Road")
member("StreetScene").deleteShader(3)

See also

newShader, shaderList

deleteTexture

Usage

member(whichCastmember).deleteTexture(whichTexture)
member(whichCastmember).deleteTexture(index)

Description

3D command; removes the texture from the cast member.

Parameters

textureNameOrNum Required. A string or integer that specifies the name or index position of the texture to delete.

Example

The first line of this example deletes the texture named Sky from the cast member named PicnicScene. The second line deletes the fifth texture of PicnicScene.

member("PicnicScene").deleteTexture("Sky")
member("PicnicScene").deleteTexture(5)

See also

newTexture
deleteVertex()  

Usage  

-- Lingo syntax  
memberObjRef.deleteVertex(indexToRemove)  

// JavaScript syntax  
memberObjRef.deleteVertex(indexToRemove);  

Description  
Vector shape command; removes an existing vertex of a vector shape cast member in the index position specified.  

Parameters  

indexToRemove Required. An integer that specifies the index position of the vertex to delete.  

Example  
This line removes the second vertex point in the vector shape Archie:  

-- Lingo syntax  
member("Archie").deleteVertex(2)  

// JavaScript syntax  
member("Archie").deleteVertex(2);  

See also  
addVertex(), moveVertex(), originMode, vertexList  

displayOpen()  

Usage  

-- Lingo syntax  
fileioObjRef.displayOpen()  

// JavaScript syntax  
fileioObjRef.displayOpen();  

Description  
Fileio method; Displays an Open dialog box.  
This method returns to script the full path and name of the selected file.  

Parameters  
None.  

See also  
Fileio
**displaySave()**

**Usage**

-- Lingo syntax
```lingo
fileioObjRef.displaySave(stringTitle, stringFileName)
```

// JavaScript syntax
```javascript
fileioObjRef.displaySave(stringTitle, stringFileName);
```

**Description**

Fileio method; Displays a Save dialog box.

This method returns to script the full path and name of the saved file.

**Parameters**

- **stringTitle** Required. A string that specifies the title displayed in the Save dialog box.
- **stringFileName** Required. A string that specifies the full path and name of the file to save.

**See also**

Fileio

**do**

**Usage**

```lingo
do stringExpression
```

**Description**

Command; evaluates a string and executes the result as a script statement. This command is useful for evaluating expressions that the user has typed and for executing commands stored in string variables, fields, arrays, and files.

Using uninitialized local variables within a do command creates a compile error. Initialize any local variables in advance.

**Note:** This command does not allow global variables to be declared; these variables must be declared in advance.

The do command works with multiple-line strings as well as single lines.

**Parameters**

- **stringExpression** Required. The string to be evaluated.

**Example**

This statement performs the statement contained within quotation marks:

```lingo
do "beep 2"
docommandList[3]
```
doneParsing()

Usage
parserObject.doneParsing()

Description
Function; returns 1 (TRUE) when the parser has completed parsing a document using parseURL(). The return value is 0 (FALSE) until the parsing is complete.

Parameters
None.

See also
parseURL()

dot()

Usage
vector1.dot(vector2)

Description
3D vector method; returns the sum of the products of the x, y, and z components of two vectors. If both vectors are normalized, the dot is the cosine of the angle between the two vectors.

To manually arrive at the dot of two vectors, multiply the x component of vector1 by the x component of vector2, then multiply the y component of vector1 by the y component of vector2, then multiply the z component of vector1 by the z component of vector2, and finally add the three products together.

This method is identical to dotProduct() function.

Parameters
vector2 Required. The second vector from which a sum is returned.

Example
In this example, the angle between the vectors pos5 and pos6 is 45 degrees. The getNormalized function returns the normalized values of pos5 and pos6, and stores them in the variables norm1 and norm2. The dot of norm1 and norm2 is 0.7071, which is the cosine of 45 degrees.

```plaintext
pos5 = vector(100, 100, 0)
pos6 = vector(0, 100, 0)
put pos5.angleBetween(pos6) -- 45.000
norm1 = pos5.getNormalized()
pumat norm1
  -- vector( 0.7071, 0.7071, 0.0000 )
norm2 = pos6.getNormalized()
pumat norm2
  -- vector( 0.0000, 1.0000, 0.0000 )
pumat norm1.dot(norm2)
  -- 0.7071
```

See also
dotProduct(), getNormalized, normalize
dotProduct()

Usage

```
vector1.dotProduct(vector2)
```

Description

3D vector method; returns the sum of the products of the x, y, and z components of two vectors. If both vectors are normalized, the dotproduct is the cosine of the angle between the two vectors.

To manually arrive at the dot of two vectors, multiply the x component of `vector1` by the x component of `vector2`, then multiply the y component of `vector1` by the y component of `vector2`, then multiply the z component of `vector1` by the z component of `vector2`, and finally add the three products together.

This method is identical to `dot()` function.

Parameters

`vector2` Required. The second vector from which a sum is returned.

Example

In this example, the angle between the vectors `pos5` and `pos6` is 45°. The `getNormalized` function returns the normalized values of `pos5` and `pos6`, and stores them in the variables `norm1` and `norm2`. The `dotProduct` of `norm1` and `norm2` is 0.7071, which is the cosine of 45°.

```
pos5 = vector(100, 100, 0)
pos6 = vector(0, 100, 0)
put pos5.angleBetween(pos6) -- 45.0000
norm1 = pos5.getNormalized()
put norm1 -- vector( 0.7071, 0.7071, 0.0000 )
norm2 = pos6.getNormalized()
put norm2 -- vector( 0.0000, 1.0000, 0.0000 )
put norm1.dotProduct(norm2) -- 0.7071
```

See also

dot(), getNormalized, normalize

downloadNetThing

Usage

```
downloadNetThing URL, localFile
```

Description

Command; copies a file from the Internet to a file on the local disk, while the current movie continues playing. Use `netDone` to find out whether downloading is finished.

Director movies in authoring mode and projectors support the `downloadNetThing` command, but the Shockwave Player does not. This protects users from unintentionally copying files from the Internet.
Although many network operations can be active at one time, running more than four concurrent operations usually slows down performance unacceptably.

Neither the Director movie's cache size nor the setting for the Check Documents option affects the behavior of the `downloadNetThing` command.

**Parameters**

- **URL** Required. The URL of any object that can be downloaded: for example, an FTP or HTTP server, an HTML page, an external cast member, a Director movie, or a graphic.
- **localFile** Required. The pathname and filename for the file on the local disk.

**Example**

These statements download an external cast member from a URL to the Director application folder and then make that file the external cast member named Cast of Thousands:

```lingo
downloadNetThing("http://www.cbDeMille.com/Thousands.cst", the applicationPath&"Thousands.Cst")
castLib("Cast of Thousands").fileName = the applicationPath&"Thousands.Cst"
```

**See also**

`importFileInto()`, `netDone()`, `preloadNetThing()`

draw()

**Usage**

```lingo
imageObjRef.draw(x1, y1, x2, y2, colorObjOrParamList)
imageObjRef.draw(point(x, y), point(x, y), colorObjOrParamList)
imageObjRef.draw(rect, colorObjOrParamList)
```

```javascript
imageObjRef.draw(x1, y1, x2, y2, colorObjOrParamList);
imageObjRef.draw(point(x, y), point(x, y), colorObjOrParamList);
imageObjRef.draw(rect, colorObjOrParamList);
```

**Description**

Image method. Draws a line or an unfilled shape with a specified color in a rectangular region of a given image object.

This method returns a value of 1 if there is no error.

If the optional parameter list is not provided, `draw()` draws a 1-pixel line between the first and second points given or between the upper left and lower right corners of the given rectangle.

For best performance, with 8-bit or lower images the color object should contain an indexed color value. For 16- or 32-bit images, use an RGB color value.

To fill a solid region, use the `fill()` method.

**Parameters**

- **x1** Required if drawing a line using x and y coordinates. An integer that specifies the x coordinate of the start of the line.
- **y1** Required if drawing a line using x and y coordinates. An integer that specifies the y coordinate of the start of the line.
$x2$ Required if drawing a line using $x$ and $y$ coordinates. An integer that specifies the $x$ coordinate of the end of the line.

$y2$ Required if drawing a line using $x$ and $y$ coordinates. An integer that specifies the $y$ coordinate of the end of the line.

`colorObjOrParamList` Required. A color object or parameter list that specifies the color of the line or shape’s border. The parameter list can be used instead of a simple color object to specify the following properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$#shapeType$</td>
<td>A symbol value of $#oval$, $#rect$, $#roundRect$, or $#line$. The default is $#line$.</td>
</tr>
<tr>
<td>$#lineSize$</td>
<td>The width of the line to use in drawing the shape.</td>
</tr>
<tr>
<td>$#color$</td>
<td>A color object, which determines the color of the shape’s border.</td>
</tr>
</tbody>
</table>

`point(x, y), point(x, y)` Required if drawing a line using points. Two points that specify the start and end points of the line.

`rect` Required if drawing a shape. A rectangle that specifies the rectangular region in which a shape is drawn.

**Example**

This statement draws a 1-pixel, dark red, diagonal line from point (0, 0) to point (128, 86) within the image of member Happy.

The following statement draws a dark red, 3-pixel unfilled oval within the image of member Happy. The oval is drawn within the rectangle (0, 0, 128, 86).

**See also**

color(), copyPixels(), fill(), image(), setPixel()

duplicate() (Image)

**Usage**

-- Lingo syntax

`imageObjRef.duplicate()`

// JavaScript syntax

`imageObjRef.duplicate();`

**Description**

Image method. Creates and returns a copy of a given image.

The new image is completely independent of the original, and is not linked to any cast member. If planning to make a lot of changes to an image, it is better to make a copy that is independent of a cast member.

**Parameters**

None.
Example

This statement creates a new image object from the image of cast member Lunar Surface and places the new image object into the variable workingImage:

```lingo
workingImage = member("Lunar Surface").image.duplicate()
```

See also

`image()`

duplicate() (list function)

Usage

```lingo
(oldList).duplicate()
duplicate(oldList)
```

Description

List function; returns a copy of a list and copies nested lists (list items that also are lists) and their contents. The function is useful for saving a list's current content.

When you assign a list to a variable, the variable contains a reference to the list, not the list itself. This means any changes to the copy also affect the original list.

To see an example of `duplicate() (list function)` used in a completed movie, see the Vector Shapes movie in the Learning/Lingo folder inside the Director application folder.

Parameters

`oldList` Required. Specifies the list to duplicate.

Example

This statement makes a copy of the list CustomersToday and assigns it to the variable CustomerRecord:

```lingo
CustomerRecord = CustomersToday.duplicate()
```

See also

`image()`

duplicate() (Member)

Usage

```
-- Lingo syntax
memberObjRef.duplicate({intPosn})

// JavaScript syntax
memberObjRef.duplicate({intPosn});
```

Description

Member method; makes a copy of a specified cast member.

This method is best used during authoring rather than during runtime; it creates another cast member in memory, which could result in memory problems.

Use this method to permanently save cast member changes with the file.
Parameters

intPosn Optional. An integer that specifies the Cast window for the duplicate cast member. If omitted, the duplicate cast member is placed in the first open Cast window position.

Example

This statement makes a copy of cast member Desk and places it in the first empty Cast window position:

-- Lingo syntax
member("Desk").duplicate()

// JavaScript syntax
member("Desk").duplicate();

This statement makes a copy of cast member Desk and places it in the Cast window at position 125:

-- Lingo syntax
member("Desk").duplicate(125)

// JavaScript syntax
member("Desk").duplicate(125);

See also

Member
duplicateFrame()

Usage

-- Lingo syntax
_movie.duplicateFrame()

// JavaScript syntax
_movie.duplicateFrame();

Description

Movie method; duplicates the current frame and its content, inserts the duplicate frame after the current frame, and then makes the duplicate frame the current frame. This method can be used during Score generation only.

This method performs the same function as the insertFrame() method.

Parameters

None.

Example

When used in the following handler, the duplicateFrame command creates a series of frames that have cast member Ball in the external cast Toys assigned to sprite channel 20. The number of frames is determined by the argument numberOfFrames.

-- Lingo syntax
on animBall(numberOfFrames)
  _movie.beginRecording()
  sprite(20).member = member("Ball", "Toys")
  repeat with i = 0 to numberOfFrames
// JavaScript syntax
function animBall(numberOfFrames) {
_movie.beginRecording();
sprite(20).member = member("Ball", "Toys");
for (var i = 0; i <= numberOfFrames; i++) {
_movie.duplicateFrame();
}
_movie.endRecording();
}

See also
insertFrame(), Movie

enableHotSpot()

Usage
-- Lingo syntax
spriteObjRef.enableHotSpot(hotSpotID, trueOrFalse)

// JavaScript syntax
spriteObjRef.enableHotSpot(hotSpotID, trueOrFalse);

Description
QTVR (QuickTime VR) command; determines whether a hot spot in a QTVR sprite is enabled (TRUE), or disabled (FALSE).

Parameters
hotSpotID Required. Specifies the hot spot in the QTVR sprite to test.
trueOrFalse Required. A TRUE or FALSE value that specifies whether the QTVR sprite is enabled.

disableHotSpot()

Usage
-- Lingo syntax
_movie.duplicateFrame()

// JavaScript syntax
_movie.duplicateFrame();

Description
Movie method; ends a Score update session.
You can resume control of Score channels through scripting after calling endRecording().

Parameters
None.
Example

When used in the following handler, the `endRecording` keyword ends the Score generation session:

-- Lingo syntax
on animBall(numberOfFrames)
    _movie.beginRecording()
    horizontal = 0
    vertical = 100
    repeat with i = 1 to numberOfFrames
        _movie.go(i)
        sprite(20).member = member("Ball")
        sprite(20).locH = horizontal
        sprite(20).locV = vertical
        sprite(20).foreColor = 255
        horizontal = horizontal + 3
        vertical = vertical + 2
        _movie.updateFrame()
    end repeat
    _movie.endRecording()
end animBall

// JavaScript syntax
function animBall(numberOfFrames) {
    _movie.beginRecording();
    var horizontal = 0;
    var vertical = 100;
    for (var i = 1; i <= numberOfFrames; i++) {
        _movie.go(i);
        sprite(20).member = member("Ball");
        sprite(20).locH = horizontal;
        sprite(20).locV = vertical;
        sprite(20).foreColor = 255;
        horizontal = horizontal + 3;
        vertical = vertical + 2;
        _movie.updateFrame();
    }
    _movie.endRecording();
}

See also

`beginRecording().Movie.updateFrame()`

erase()

Usage

-- Lingo syntax
member0ObjRef.erase()

// JavaScript syntax
member0ObjRef.erase();

Description

Member method; deletes a specified cast member and leaves its slot in the Cast window empty. For best results, use this method during authoring and not in projectors. Using this method in projectors may cause memory problems.
Parameters

None.

Example

This statement deletes the cast member named Gear in the Hardware cast:

-- Lingo syntax
member("Gear", "Hardware").erase()

// JavaScript syntax
member("Gear", "Hardware").erase();

This handler deletes cast members numbered from start through finish:

-- Lingo syntax
on deleteMember start, finish
    repeat with i = start to finish
        member(i).erase()
    end repeat
end deleteMember

// JavaScript syntax
function deleteMember(start, finish) {
    for (var i=start; i<=finish; i++) {
        member(i).erase();
    }
}

See also

Member, new()

error()

Usage

-- Lingo syntax
fileioObjRef.error(intError)

// JavaScript syntax
fileioObjRef.error(intError);

Description

Fileio method; Returns a specified error message.

Parameters

intError Required. An integer that specifies the error. Valid values include 0 ("OK") or 1 ("Memory allocation failure"). All other values return "Unknown error".

See also

Fileio
**externalEvent()**

**Usage**

`externalEvent "string"`

**Description**

Command; sends a string to the browser that the browser can interpret as a scripting language instruction, allowing a movie playing or a browser to communicate with the HTML page in which it is embedded.

This command works only for movies in browsers.

*Note:* The `externalEvent` command does not produce a return value. There is no immediate way to determine whether the browser handled the event or ignored it. Use on `EvalScript` within the browser to return a message to the movie.

**Parameters**

- `string` Required. The string to send to the browser. This string must be in a scripting language supported by the browser.

**Example**

The following statements use `externalEvent` in the LiveConnect scripting environment, which is supported by Netscape 3.x and later.

LiveConnect evaluates the string passed by `externalEvent` as a function call. JavaScript authors must define and name this function in the HTML header. In the movie, the function name and parameters are defined as a string in `externalEvent`. Because the parameters must be interpreted by the browser as separate strings, each parameter is surrounded by single quotation marks.

Statements within HTML:

```javascript
function MyFunction(parm1, parm2) {
  //script here
}
```

Statements within a script in the movie:

```javascript
externalEvent ("MyFunction('parm1','parm2')")
```

The following statements use `externalEvent` in the ActiveX scripting environment used by Internet Explorer in Windows. ActiveX treats `externalEvent` as an event and processes this event and its string parameter the same as an `onClick` event in a button object.

- Statements within HTML:

In the HTML header, define a function to catch the event; this example is in VBScript:

```vbnet
Sub NameOfShockwaveInstance_externalEvent(aParam)
  'script here
End Sub
```
Alternatively, define a script for the event:

```
<SCRIPT FOR="NameOfShockwaveInstance"
EVENT="externalEvent(aParam)"
LANGUAGE="VBScript">
  'script here
</SCRIPT>
```

Within the movie, include the function and any parameters as part of the string for `externalEvent`:

```
externalEvent ("MyFunction ('parm1','parm2')")
```

See also

on EvalScript

extrude3D

Usage

```
member(whichTextCastmember).extrude3D(member(which3dCastmember))
```

Description

3D command; creates a new #extruder model resource in a 3D cast member from the text in a text cast member.

This is not the same as using the 3D displayMode property of a text cast member.

To create a model using extrude3D:

1. Create a new #extruder model resource in a 3D cast member:
   ```
   textResource = member("textMember").extrude3D(member("3DMember"))
   ```

2. Create a new model using the model resource created in step 1:
   ```
   member("3DMember").newModel("myText", textResource)
   ```

Parameters

- `which3dCastmember` Required. The cast member within which a new #extruder model resource is created.

Example

In this example, Logo is a text cast member and Scene is a 3D cast member. The first line creates a model resource in Scene which is a 3D version of the text in Logo. The second line uses this model resource to create a model named 3dLogo.

```
myTextModelResource = member("Logo").extrude3D(member("Scene"))
member("Scene").newModel("3dLogo", myTextModelResource)
```

externalParamName()

Usage

-- Lingo syntax
_player.externalParamName(paramNameOrNum)

// JavaScript syntax
_player.externalParamName(paramNameOrNum);

Description

Player method; returns the name of a specified parameter in the list of external parameters from an HTML <EMBED> or <OBJECT> tag.

If specifying a parameter by name, this method returns any parameter names that matches paramNameOrNum. The match is not case sensitive. If no matching parameter name is found, this method returns VOID (Lingo) or null (JavaScript syntax).

If specifying a parameter by number, this method returns the parameter name at the paramNameOrNum position in the parameter list. If no matching parameter position is found, this method returns VOID or null.

This method is valid only for movies with Shockwave content that are running in a browser. It cannot be used with Director movies or projectors.

The following list describes the pre-defined external parameters that can be used.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>swAudio</td>
<td>A string that specifies the location of a Shockwave Audio file to be played with the movie. The value is a fully qualified URL.</td>
</tr>
<tr>
<td>swBackColor</td>
<td>A color value intended to modify the movie’s Stage color property. The value is any integer value from 0 to 255. Use 0 to 255 for movies in 8-bit color, and 0 to 15 for movies in 4-bit color.</td>
</tr>
<tr>
<td>swBanner</td>
<td>A string that specifies the text to be used as a banner in the movie.</td>
</tr>
<tr>
<td>swColor</td>
<td>A color value for use in modifying the color of a specific object. The value is any integer from 0 to 255. Use 0 to 255 for movies in 8-bit color, and 0 to 15 for movies in 4-bit color.</td>
</tr>
<tr>
<td>swForeColor</td>
<td>A new foreground color value. Text written into field cast members is rendered in the currently active foreground color. The value is any integer value from 0 to 255. Use 0 to 255 for movies in 8-bit color, and 0 to 15 for movies in 4-bit color.</td>
</tr>
<tr>
<td>swFrame</td>
<td>A string value that is the name assigned to a given frame in the movie.</td>
</tr>
<tr>
<td>swList</td>
<td>A comma-delimited list of items that can be parsed with script. List values may be key/value pairs, Boolean items, integers, or strings.</td>
</tr>
<tr>
<td>swName</td>
<td>A name, such as a user name, to be displayed or used within the movie.</td>
</tr>
<tr>
<td>swPassword</td>
<td>A password, perhaps for use in conjunction with the swName property, to be used within the movie.</td>
</tr>
<tr>
<td>swPreloadTime</td>
<td>An integer value which specifies the number of seconds of an audio file sound that should be preloaded before the sound begins to play. Used with Shockwave Audio to improve playback performance by increasing the amount of audio already downloaded before playback begins.</td>
</tr>
</tbody>
</table>
Parameters

- **paramNameOrNum** Required. A string that specifies the name of the parameter name to return, or an integer that specifies the index location of the parameter name to return.

Example

This statement places the value of a given external parameter in the variable `myVariable`:

```lingo
-- Lingo syntax
if (_player.externalParamName("swURL") = "swURL") then
  myVariable = _player.externalParamName("swURL")
end if
```

```javascript
// JavaScript syntax
if (_player.externalParamName("swURL") == "swURL") {
  var myVariable = _player.externalParamName("swURL");
}
```

`externalParamValue()`, `Movie`

### externalParamValue()

#### Usage

- **Lingo syntax**
  
  ```lingo
  _player.externalParamValue(paramNameOrNum)
  ```

- **JavaScript syntax**
  
  ```javascript
  _player.externalParamValue(paramNameOrNum);
  ```

#### Description

Returns the value of a specified parameter in the list of external parameters from an HTML `<EMBED>` or `<OBJECT>` tag.

If specifying a parameter value by name, this method returns the value of the first parameter whose name matches `paramNameOrNum`. The match is not case sensitive. If no matching parameter value is found, this method returns `VOID` (Lingo) or `null` (JavaScript syntax).

If specifying a parameter value by index, this method returns the value of the parameter at the `paramNameOrNum` position in the parameter list. If no matching parameter position is found, this method returns `VOID` or `null`.

---

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>swSound</code></td>
<td>A string value which may specify the name of a sound in the Director movie to be played, or whether or not a sound should be played at all.</td>
</tr>
<tr>
<td><code>swText</code></td>
<td>A string value that specifies text to be used in the movie.</td>
</tr>
<tr>
<td><code>swURL</code></td>
<td>A string URL that may specify the location of another movie with Shockwave content or Shockwave Audio file.</td>
</tr>
<tr>
<td><code>swVolume</code></td>
<td>An integer value (0 to 10 is recommended) that is used to control the volume level of the sound output from the movie. 0 is off (no sound), 10 is maximum volume.</td>
</tr>
<tr>
<td><code>sw1</code> through <code>sw9</code></td>
<td>Nine additional properties for author-defined parameters.</td>
</tr>
</tbody>
</table>
This method is valid only for movies with Shockwave content that are running in a browser. It cannot be used with Director movies or projectors.

The following list describes the pre-defined external parameters that can be used.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>swAudio</td>
<td>A string that specifies the location of a Shockwave Audio file to be played with the movie. The value is a fully qualified URL.</td>
</tr>
<tr>
<td>swBackColor</td>
<td>A color value intended to modify the movie’s Stage color property. The value is any integer value from 0 to 255. Use 0 to 255 for movies in 8-bit color, and 0 to 15 for movies in 4-bit color.</td>
</tr>
<tr>
<td>swBanner</td>
<td>A string that specifies the text to be used as a banner in the movie.</td>
</tr>
<tr>
<td>swColor</td>
<td>A color value for use in modifying the color of a specific object. The value is any integer from 0 to 255. Use 0 to 255 for movies in 8-bit color, and 0 to 15 for movies in 4-bit color.</td>
</tr>
<tr>
<td>swForeColor</td>
<td>A new foreground color value. Text written into field cast members is rendered in the currently active foreground color. The value is any integer value from 0 to 255. Use 0 to 255 for movies in 8-bit color, and 0 to 15 for movies in 4-bit color.</td>
</tr>
<tr>
<td>swFrame</td>
<td>A string value that is the name assigned to a given frame in the movie.</td>
</tr>
<tr>
<td>swList</td>
<td>A comma-delimited list of items that can be parsed with script. List values may be key/value pairs, Boolean items, integers, or strings.</td>
</tr>
<tr>
<td>swName</td>
<td>A name, such as a user name, to be displayed or used within the movie.</td>
</tr>
<tr>
<td>swPassword</td>
<td>A password, perhaps for use in conjunction with the swName property, to be used within the movie.</td>
</tr>
<tr>
<td>swPreloadTime</td>
<td>An integer value which specifies the number of seconds of an audio file sound that should be preloaded before the sound begins to play. Used with Shockwave Audio to improve playback performance by increasing the amount of audio already downloaded before playback begins.</td>
</tr>
<tr>
<td>swSound</td>
<td>A string value which may specify the name of a sound in the Director movie to be played, or whether or not a sound should be played at all.</td>
</tr>
<tr>
<td>swText</td>
<td>A string value that specifies text to be used in the movie.</td>
</tr>
<tr>
<td>swURL</td>
<td>A string URL that may specify the location of another Shockwave movie or Shockwave Audio file.</td>
</tr>
<tr>
<td>swVolume</td>
<td>An integer value (0 to 10 is recommended) that is used to control the volume level of the sound output from the movie. 0 is off (no sound), 10 is maximum volume.</td>
</tr>
<tr>
<td>sw1 through sw9</td>
<td>Nine additional properties for author-defined parameters.</td>
</tr>
</tbody>
</table>

**Parameters**

`paramNameOrNum` Required. A string that specifies the name of the parameter value to return, or an integer that specifies the index location of the parameter value to return.
Example

This statement places the value of an external parameter in the variable myVariable:

```
-- Lingo syntax
if (_player.externalParamName("swURL") = "swURL") then
    myVariable = _player.externalParamValue("swURL")
end if

// JavaScript syntax
if (_player.externalParamName("swURL") == "swURL") {
    var myVariable = _player.externalParamValue("swURL");
}
```

See also

`externalParamName()`, `Movie`

extractAlpha()

**Usage**

`imageObject.extractAlpha()`

**Description**

This function copies the alpha channel from the given 32-bit image and returns it as a new image object. The result is an 8-bit grayscale image representing the alpha channel.

This function is useful for down-sampling 32-bit images with alpha channels.

Example

This statement places the alpha channel of the image of member 1 into the variable `mainAlpha`:

```
mainAlpha = member(1).image.extractAlpha()
```

`setAlpha()`, `useAlpha`

fadeln()

**Usage**

```
-- Lingo syntax
soundChannelObjRef.fadeln({intMilliseconds})

// JavaScript syntax
soundChannelObjRef.fadeln({intMilliseconds});
```

**Description**

Sound Channel method; immediately sets the volume of a sound channel to zero and then brings it back to the current volume over a given number of milliseconds.

The current pan setting is retained for the entire fade.

**Parameters**

`intMilliseconds` Optional. An integer that specifies the number of milliseconds over which the volume is increased back to its original value. The default is 1000 milliseconds (1 second) if no value is given.
Example

This Lingo fades in sound channel 3 over a period of 3 seconds from the beginning of cast member introMusic2:

-- Lingo syntax
sound(3).play(member("introMusic2"))
sound(3).fadeIn(3000)

// JavaScript syntax
sound(3).play(member("introMusic2"));
sound(3).fadeIn(3000);

See also
fadeOut(), fadeTo(), pan, Sound Channel, volume (Windows Media)

fadeOut()

Usage

-- Lingo syntax
soundChannelObjRef.fadeOut({intMilliseconds})

// JavaScript syntax
soundChannelObjRef.fadeOut({intMilliseconds});

Description

Sound Channel method; gradually reduces the volume of a sound channel to zero over a given number of milliseconds.

The current pan setting is retained for the entire fade.

Parameters

intMilliseconds Optional. An integer that specifies the number of milliseconds over which the volume is reduced to zero. The default is 1000 milliseconds (1 second) if no value is given.

Example

This statement fades out sound channel 3 over a period of 5 seconds:

-- Lingo syntax
sound(3).fadeOut(5000)

// JavaScript syntax
sound(3).fadeOut(5000);

See also
fadeOut(), fadeTo(), pan, Sound Channel, volume (Windows Media)
**fadeTo()**

**Usage**

-- Lingo syntax
```
soundChannelObjRef.fadeTo(intVolume [, intMilliseconds])
```

// JavaScript syntax
```
soundChannelObjRef.fadeTo(intVolume [, intMilliseconds]);
```

**Description**

Sound Channel method; gradually changes the volume of a sound channel to a specified volume over a given number of milliseconds.

The current pan setting is retained for the entire fade.

To see an example of `fadeTo()` used in a completed movie, see the Sound Control movie in the Learning/Lingo folder inside the Director application folder.

**Parameters**

- `intVolume` Required. An integer that specifies the volume level to change to. The range of values for `intVolume` is 0 to 255.
- `intMilliseconds` Optional. An integer that specifies the number of milliseconds over which the volume is changed to `intVolume`. The default value is 1000 milliseconds (1 second) if no value is given.

**Example**

The following statement changes the volume of sound channel 4 to 150 over a period of 2 seconds. It can be a fade up or a fade down, depending on the original volume of sound channel 4 when the fade begins.

-- Lingo syntax
```
sound(4).fadeTo(150, 2000)
```

// JavaScript syntax
```
sound(4).fadeTo(150, 2000);
```

**See also**

`fadeIn()`, `fadeOut()`, `pan`, `Sound Channel`, `volume (Windows Media)`

**fileName()**

**Usage**

-- Lingo syntax
```
fileIOObjRef.fileName()
```

// JavaScript syntax
```
fileIOObjRef.fileName();
```

**Description**

Fileio method; Returns the full path and name of an open file.

You must first open a file by calling `openFile()` before using `fileName()` to return the file's name.
Parameters

None.

See also

Fileio, openFile()

fill()

Usage

-- Lingo syntax
imageObjRef.fill(left, top, right, bottom, colorObjOrParamList)
imageObjRef.fill(point(x, y), point(x, y), colorObjOrParamList)
imageObjRef.fill(rect, colorObjOrParamList)

// JavaScript syntax
imageObjRef.fill(left, top, right, bottom, colorObjOrParamList);
imageObjRef.fill(point(x, y), point(x, y), colorObjOrParamList);
imageObjRef.fill(rect, colorObjOrParamList);

Description

Image method. Fills a rectangular region with a specified color in a given image object.

This method returns a value of 1 if there is no error, zero if there is an error.

For best performance, with 8-bit or lower images the color object should contain an indexed color value. For 16-32-bit images, use an RGB color value.

Parameters

left Required if filling a region specified by coordinates. An integer that specifies the left side of the region to fill.

top Required if filling a region specified by coordinates. An integer that specifies the top side of the region to fill.

right Required if filling a region specified by coordinates. An integer that specifies the right side of the region to fill.

bottom Required if filling a region specified by coordinates. An integer that specifies the bottom side of the region to fill.

colorObjOrParamList Required. A color object or parameter list that specifies the color used to fill the region. The parameter list can be used instead of a simple color object to specify the following properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#shapeType</td>
<td>A symbol value of #oval, #rect, #roundRect, or #line. The default is #line.</td>
</tr>
<tr>
<td>#lineSize</td>
<td>The width of the line to use in drawing the shape.</td>
</tr>
<tr>
<td>#color</td>
<td>A color object, which determines the fill color of the region.</td>
</tr>
<tr>
<td>#bgColor</td>
<td>A color object, which determines the color of the region's border.</td>
</tr>
</tbody>
</table>
point(x, y), point(x, y) Required if filling a region using points. Two points that specify the upper-left and lower-right corners of region to fill, relative to the upper-left corner of the given image object.

rect Required if filling a region using a rectangle. A rectangle that specifies the rectangular region to fill.

Example

This statement renders the image object in the variable myImage completely black:
The following statement draws a filled oval in the image object TestImage. The oval has a green fill and a 5-pixel-wide red border.

See also
color(), draw(), image()

findLabel()

Usage

-- Lingo syntax
spriteObjRef.findLabel(whichLabelName)

// JavaScript syntax
spriteObjRef.findLabel(whichLabelName);

Description

Function: this function returns the frame number (within the Flash movie) that is associated with the label name requested.
A 0 is returned if the label doesn’t exist, or if that portion of the Flash movie has not yet been streamed in.

Parameters

whichLabelName Required. Specifies the frame label to find.

findEmpty()

Usage

-- Lingo syntax
castObjRef.findEmpty({memberObjRef})

// JavaScript syntax
castObjRef.findEmpty({memberObjRef});

Description

Cast library method; displays the next empty cast member position or the position after a specified cast member.
This method is available only on the current cast library.

Parameters

memberObjRef Optional. A reference to the cast member after which the next empty cast member position is displayed. If omitted, the next empty cast member position is displayed.
Example

This statement finds the first empty cast member on or after cast member 100:

-- Lingo syntax
trace(castLib(1).findEmpty(member(100)))

// JavaScript syntax
trace(castLib(1).findEmpty(member(100)));

See also
Cast Library, Member

findPos

Usage

list.findPos(property)
findPos(list, property)

Description

List command; identifies the position of a property in a property list.

Using findPos with linear lists returns a bogus number if the value of property is a number and a script error if the value of property is a string.

The findPos command performs the same function as the findPosNear command, except that findPos is VOID when the specified property is not in the list.

Parameters

property Required. The property whose position is identified.

Example

This statement identifies the position of the property c in the list Answers, which consists of [#a:10, #b:12, #c:15, #d:22]:

Answers.findPos(#c)

The result is 3, because c is the third property in the list.

See also
findPosNear, sort

findPosNear

Usage

sortedList.findPosNear(valueOrProperty)
findPosNear(sortedList, valueOrProperty)

Description

List command; for sorted lists only, identifies the position of an item in a specified sorted list.

The findPosNear command works only with sorted lists. Replace valueOrProperty with a value for sorted linear lists, and with a property for sorted property lists.
The `findPosNear` command is similar to the `findPos` command, except that when the specified property is not in the list, the `findPosNear` command identifies the position of the value with the most similar alphanumeric name. This command is useful in finding the name that is the closest match in a sorted directory of names.

Parameters

valueOrProperty Required. The value or property whose position is identified.

Example

This statement identifies the position of a property in the sorted list `Answers`, which consists of 
[#Nile:2, #Pharaoh:4, #Raja:0]:
Answers.findPosNear(#N1)
The result is 1, because Ni most closely matches Nile, the first property in the list.

See also

`findPos`

finishIdleLoad()

Usage

-- Lingo syntax
_movie.finishIdleLoad(intLoadTag)

// JavaScript syntax
_movie.finishIdleLoad(intLoadTag);

Description

Movie method; forces completion of loading for all the cast members that have the specified load tag.

Parameters

intLoadTag Required. An integer that specifies the load tag of the cast members to be loaded.

Example

This statement completes the loading of all cast members that have the load tag 20:

-- Lingo syntax
_movie.finishIdleLoad(20)

// JavaScript syntax
_movie.finishIdleLoad(20);

See also

`IdleHandlerPeriod`, `idleLoadDone()`, `idleLoadMode`, `idleLoadPeriod`, `idleLoadTag`, `idleReadChunkSize`, `Movie`
**flashToStage()**

**Usage**

--- Lingo syntax
```
spriteObjRef.flashToStage(pointInFlashMovie)
```

// JavaScript syntax
```
spriteObjRef.flashToStage(pointInFlashMovie);
```

**Description**

Function; returns the coordinate on the Director Stage that corresponds to a specified coordinate in a Flash movie sprite. The function accepts both the Flash channel and movie coordinate and returns the Director Stage coordinate as Director point values: for example, point(300,300).

Flash movie coordinates are measured in Flash movie pixels, which are determined by a movie's original size when it was created in Flash. For the purpose of calculating Flash movie coordinates, point(0,0) of a Flash movie is always at its upper left corner. (The cast member's originPoint property is used only for rotation and scaling, not to calculate movie coordinates.)

The `flashToStage` and the corresponding `stageToFlash` functions are helpful for determining which Flash movie coordinate is directly over a Director Stage coordinate. For both Flash and Director, point(0,0) is the upper left corner of the Flash Stage or Director Stage. These coordinates may not match on the Director Stage if a Flash sprite is stretched, scaled, or rotated.

**Parameters**

*pointInFlashMovie* Required. The point in the Flash movie sprite whose coordinates are returned.

**Example**

This handler accepts a point value and a sprite reference as a parameter, and it then sets the upper left coordinate of the specified sprite to the specified point within a Flash movie sprite in channel 10:

--- Lingo syntax
```
on snapSprite(whichFlashPoint, whichSprite)
    sprite(whichSprite).loc = sprite(1).FlashToStage(whichFlashPoint)
    _movie.updatestage()
end
```

// JavaScript syntax
```
function snapSprite(whichFlashPoint, whichSprite) {
    sprite(whichSprite).loc = sprite(1).FlashToStage(whichFlashPoint);
    _movie.updateStage();
}
```

**See also**

*stageToFlash()*
float()  

**Usage**  
(expression).float  
float(expression)  

**Description**  
Function (Lingo only); converts an expression to a floating-point number. The number of digits that follow the decimal point (for display purposes only, calculations are not affected) is set using the floatPrecision property. 
In JavaScript syntax, use the parseFloat() function.

**Parameters**  
*expression* Required. The expression to convert to a floating-point number.

**Example**  
This statement converts the integer 1 to the floating-point number 1:  
put (1).float  
-- 1.0  

Math operations can be performed using float; if any of the terms is a float value, the entire operation is performed with float:  
"the floatPrecision = 1  
put 2 + 2  
-- 4  
put (2).float + 2  
-- 4.0  
the floatPrecision = 4  
put 22/7  
-- 3  
put (22).float / 7  
-- 3.1429"  

**See also**  
floatPrecision, ilk()  

floatP()  

**Usage**  
(expression).floatP  
floatP(expression)  

**Description**  
Function (Lingo only); indicates whether an expression is a floating-point number (1 or TRUE) or not (0 or FALSE).  
The *P* in floatP stands for *predicate*.  

**Parameters**  
*expression* Required. The expression to test.
Example

This statement tests whether 3.0 is a floating-point number. The Message window displays the number 1, indicating that the statement is **TRUE**.

```
put (3.0).floatP
-- 1
```

This statement tests whether 3 is a floating-point number. The Message window displays the number 0, indicating that the statement is **FALSE**.

```
put (3).floatP
-- 0
```

See also

- `float()`, `ilk()`, `integerP()`, `objectP()`, `stringP()`, `symbolP()`

flushInputEvents()

Usage

```
-- Lingo syntax
_player.flushInputEvents()

// JavaScript syntax
_player.flushInputEvents();
```

Description

Player method; flushes any waiting mouse or keyboard events from the Director message queue. Generally this is useful when script is in a tight loop and the author wants to make sure any mouse clicks or keyboard presses don’t get through.

This method operates at runtime only and has no effect during authoring.

Parameters

None.

Example

This statement disables mouse and keyboard events while a repeat loop executes:

```
-- Lingo syntax
repeat with i = 1 to 10000
  _player.flushInputEvents()
  sprite(1).loc = sprite(1).loc + point(1, 1)
end repeat

// JavaScript syntax
for (var i = 1; i <= 10000; i++) {
  _player.flushInputEvents();
  sprite(1).loc = sprite(1).loc + point(1, 1);
}
```

See also

- `on keyDown`, `on keyUp`, `on mouseDown (event handler)`, `on mouseUp (event handler)`, `Player`
forget() (Window)

Usage

-- Lingo syntax
windowObjRef.forget()

// JavaScript syntax
windowObjRef.forget();

Description

Window method; instructs script to close a window and stop its playback when it's no longer in use and no other variables refer to it.

Calling `forget()` on a window also removes that window's reference from the `windowList`.

When the `forget()` method is called, the window and the movie in a window (MIAW) disappear without calling the `stopMovie`, `closeWindow`, or `deactivateWindow` handlers.

If there are many global references to the movie in a window, the window doesn't respond to the `forget()` method.

Parameters

None.

Example

This statement instructs Lingo to delete the window Control Panel when the movie no longer uses the window:

-- Lingo syntax
window("Control Panel").forget()

// JavaScript syntax
window("Control Panel").forget();

See also

close(), open() (Window), Window, windowList

forget() (Timeout)

Usage

timeout("timeoutName").forget()
forget(timeout("timeoutName"))

Description

This timeout object function removes a timeout object from the `timeoutList`, and prevents it from sending further timeout events.

Parameters

None.
Example

This statement deletes the timeout object named AlarmClock from the timeoutList:

timeout("AlarmClock").forget()

See also

timeout(), timeoutHandler, timeoutList, new()

framesToHMS()

Usage

framesToHMS(frames, tempo, dropFrame, fractionalSeconds)

Description

Function; converts the specified number of frames to their equivalent length in hours, minutes, and seconds. This function is useful for predicting the actual playtime of a movie or controlling a video playback device.

The resulting string uses the form sHH:MM:SS.FFD, where:

<table>
<thead>
<tr>
<th>s</th>
<th>A character is used if the time is less than zero, or a space if the time is greater than or equal to zero.</th>
</tr>
</thead>
<tbody>
<tr>
<td>HH</td>
<td>Hours.</td>
</tr>
<tr>
<td>MM</td>
<td>Minutes.</td>
</tr>
<tr>
<td>SS</td>
<td>Seconds.</td>
</tr>
<tr>
<td>FF</td>
<td>Indicates a fraction of a second if fractionalSeconds is TRUE or frames if fractionalSeconds is FALSE.</td>
</tr>
<tr>
<td>D</td>
<td>A “d” is used if dropFrame is TRUE, or a space if dropFrame is FALSE.</td>
</tr>
</tbody>
</table>

Parameters

frames Required. An integer expression that specifies the number of frames.

tempo Required. An integer expression that specifies the tempo in frames per second.

dropFrame Required. Compensates for the color NTSC frame rate, which is not exactly 30 frames per second and is meaningful only if FPS is set to 30 frames per second. Normally, this parameter is set to FALSE.

fractionalSeconds Required. Determines whether the residual frames are converted to the nearest hundredth of a second (TRUE) or returned as an integer number of frames (FALSE).

Example

The following statement converts a 2710-frame, 30 frame-per-second movie. The dropFrame and fractionalSeconds arguments are both turned off:

put framesToHMS(2710, 30, FALSE, FALSE)

-- * 00:01:30.10 *

See also

HMStoFrames()
frameReady() (Movie)

Usage

-- Lingo syntax
_movie.frameReady(intFrameNum)
_movie.frameReady(frameNumA, frameNumB)

// JavaScript syntax
_movie.frameReady(intFrameNum);
_movie.frameReady(frameNumA, frameNumB);

Description

Movie method; for Director movies, projectors, and movies with Shockwave content, determines whether the cast members of a frame or range of frames have been downloaded.

This method returns TRUE if the specified cast members have been downloaded, and FALSE if not.

For a demonstration of the frameReady() method used in a Director movie, see the sample movie “Streaming Shockwave” in Director Help.

Parameters

intFrameNum Optional if testing whether a single frame’s cast members have been downloaded. An integer that specifies the individual frame to test. If omitted, frameReady() determines whether the cast members used in any frame of a Score have been downloaded.

frameNumA Required if testing whether the cast members in a range of frames have been downloaded. An integer that specifies the first frame in the range.

frameNumB Required if testing whether the cast members in a range of frames have been downloaded. An integer that specifies the last frame in the range.

Example

This statement determines whether the cast members for frame 20 are downloaded and ready to be viewed:

-- Lingo syntax
on exitFrame
  if (_movie.frameReady(20)) then
    _movie.go(20)
  else
    _movie.go(1)
  end if
end

// JavaScript syntax
function exitFrame() {  
  if (_movie.frameReady(20)) {
    _movie.go(20);
  } else {
    _movie.go(1);
  }
}
The following frame script checks to see if frame 25 of a Flash movie sprite in channel 5 can be rendered. If it can't, the script keeps the playhead looping in the current frame of the Director movie. When frame 25 can be rendered, the script starts the movie and lets the playhead proceed to the next frame of the Director movie.

See also
mediaReady, Movie

frameStep()

Usage
-- Lingo syntax
dvdObjRef.frameStep(intFrames)

// JavaScript syntax
dvdObjRef.frameStep(intFrames);

Description
DVD method; steps forward from the current location a specified number of frames.

Parameters
intFrames Required. An integer that specifies the number of frames to step forward.

Example
This statements jumps 100 frames forward:

-- Lingo syntax
member("drama").frameStep(100)

// JavaScript syntax
member("drama").frameStep(100);

See also
DVD

freeBlock()

Usage
the freeBlock

Description
Function; indicates the size of the largest free contiguous block of memory, in bytes. A kilobyte (K) is 1024 bytes. A megabyte (MB) is 1024 kilobytes. Loading a cast member requires a free block at least as large as the cast member.

Parameters
None.
Example

This statement determines whether the largest contiguous free block is smaller than 10K and displays an alert if it is:

```-- Lingo syntax
if (the freeBlock < (10 * 1024)) then alert "Not enough memory!"
```

```// JavaScript syntax
if (freeBlock < (10 * 1024)) {
    alert("Not enough memory!")
}
```

See also

*freeBytes()* · *memorySize* · *ramNeeded()* · *size*

**freeBytes()**

**Usage**

`the freeBytes`

**Description**

Function; indicates the total number of bytes of free memory, which may not be contiguous. A kilobyte (K) is 1024 bytes. A megabyte (MB) is 1024 kilobytes.

This function differs from *freeBlock* in that it reports all free memory, not just contiguous memory.

On the Macintosh, selecting Use System Temporary Memory in the Director General Preferences or in a projector's Options dialog box tells the *freeBytes* function to return all the free memory that is available to the application. This amount equals the application's allocation shown in its Get Info dialog box and the Largest Unused Block value in the About This Macintosh dialog box.

**Parameters**

None.

**Example**

This statement checks whether more than 200K of memory is available and plays a color movie if it is:

```if (the freeBytes > (200 * 1024)) then play movie "colorMovie"
```

See also

*freeBlock()* · *memorySize* · *objectP()* · *ramNeeded()* · *size*
generateNormals()

Usage

```plaintext
member(whichCastmember).modelResource(whichModelResource).
generateNormals(style)
```

Description

3D #mesh model resource command; calculates the normal vectors for each vertex of the mesh.

If the style parameter is set to #flat, each vertex receives a normal for each face to which it belongs. Furthermore, all three of the vertices of a face will have the same normal. For example, if the vertices of face[1] all receive normal[1] and the vertices of face[2] all receive normal[2], and the two faces share vertex[8], then the normal of vertex[8] is normal[1] in face[1] and normal[2] in face[2]. Use of the #flat parameter results in very clear delineation of the faces of the mesh.

If the style parameter is set to #smooth, each vertex receives only one normal, regardless of the number of faces to which it belongs, and the three vertices of a face can have different normals. Each vertex normal is the average of the face normals of all of the faces that share the vertex. Use of the #smooth parameter results in a more rounded appearance of the faces of the mesh, except at the outer edges of the faces at the silhouette of the mesh, which are still sharp.

A vertex normal is a direction vector which indicates the “forward” direction of a vertex. If the vertex normal points toward the camera, the colors displayed in the area of the mesh controlled by that normal are determined by the shader. If the vertex normal points away from the camera, the area of the mesh controlled by that normal will be non-visible.

After using the generateNormals() command, you must use the build() command to rebuild the mesh.

Parameters

- **style** Required. A symbol that specifies the style of the vertex.

Example

The following statement calculates vertex normals for the model resource named FloorMesh. The style parameter is set to #smooth, so each vertex in the mesh will receive only one normal.

```plaintext
member("Room").modelResource("FloorMesh").generateNormals(#smooth)
```

See also

- build(). face[]. normalList. normals. flat
**getaProp**

**Usage**

```l hooks; getaProp(list, item) list[listPosition] propertyList [ #propertyName ] propertyList [ "propertyName" ]```

**Description**

List command; for linear and property lists, identifies the value associated with the item specified by `item`, `listPosition`, or `propertyName` in the list specified by `list`.

- When the list is a linear list, replace `item` with the number for an item's position in a list as shown by `listPosition`. The result is the value at that position.
- When the list is a property list, replace `item` with a property in the list as in `propertyName`. The result is the value associated with the property.

The `getaProp` command returns `VOID` when the specified value is not in the list.

When used with linear lists, the `getaProp` command has the same function as the `getAt` command.

**Parameters**

- `itemNameOrNum` Required. For linear lists, an integer that specifies the index position of the value in the list to return; for property lists, a symbol (Lingo) or a string (JavaScript syntax) that specifies the property whose value is returned.

**Example**

This statement identifies the value associated with the property #joe in the property list ages, which consists of [#john:10, #joe:12, #cheryl:15, #barbara:22]:

```l hooks; put getaProp(ages, #joe)`

The result is 12, because this is the value associated with the property #joe.

The same result can be achieved using bracket access on the same list:

```l hooks; put ages[#joe]```

The result is again 12.

If you want the value at a certain position in the list, you can also use bracket access. To get the third value in the list, associated with the third property, use this syntax:

```l hooks; put ages[3] -- 15```

**Note:** Unlike the `getAProp` command where `VOID` is returned when a property doesn't exist, a script error will occur if the property doesn't exist when using bracket access.

**See also**

- `getAt`, `getOne()`, `getProp()`, `setaProp`, `setAt`
getAt

Usage
getAt(list, position)
list [position]

Description
List command; identifies the item in a specified position of a specified list. If the list contains fewer elements than the specified position, a script error occurs.

The getAt command works with linear and property lists. This command has the same function as the getaProp command for linear lists.

This command is useful for extracting a list from within another list, such as the deskTopRectList.

Parameters
list Required. Specifies the list from in which the item exists.
position Required. Specifies the index position of the item in the list.

Example
This statement causes the Message window to display the third item in the answers list, which consists of [10, 12, 15, 22]:
put getAt(answers, 3)
-- 15

The same result can be returned using bracket access:
put answers[3]
-- 15

The following example extracts the first entry in a list containing two entries that specify name, department, and employee number information. Then the second element of the newly extracted list is returned, identifying the department in which the first person in the list is employed. The format of the list is [[“Dennis”, “consulting”, 510], [“Sherry”, “Distribution”, 973]], and the list is called employeeInfoList.

firstPerson = getAt(employeeInfoList, 1)
put firstPerson
-- [“Dennis”, “consulting”, 510]
firstPersonDept = getAt(firstPerson, 2)
put firstPersonDept
-- “consulting”

It’s also possible to nest getAt commands without assigning values to variables in intermediate steps. This format can be more difficult to read and write, but less verbose.

firstPersonDept = getAt(getAt(employeeInfoList, 1), 2)
put firstPersonDept
-- “consulting”
You can also use the bracket list access:

```lingo
firstPerson = employeeInfoList[1]
put firstPerson
-- ['Dennis', 'consulting', 510]
```

```lisp
firstPersonDept = firstPerson[2]
put firstPersonDept
-- 'consulting'
```

As with `getAt`, brackets can be nested:

```lisp
firstPersonDept = employeeInfoList[1][2]
```

`getaProp, setaProp, setAt`

### `getError()` (Flash, SWA)

#### Usage

```
-- Lingo syntax
memberObjRef.getError()
```

```
// JavaScript syntax
memberObjRef.getError();
```

#### Description

Function; for Shockwave Audio (SWA) or Flash cast members, indicates whether an error occurred as the cast member streamed into memory and returns a value.

Shockwave Audio cast members have the following possible `getError()` integer values and corresponding `getErrorString()` messages:

<table>
<thead>
<tr>
<th><code>getError()</code> value</th>
<th><code>getErrorString()</code> message</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>OK</td>
</tr>
<tr>
<td>1</td>
<td>memory</td>
</tr>
<tr>
<td>2</td>
<td>network</td>
</tr>
<tr>
<td>3</td>
<td>playback device</td>
</tr>
<tr>
<td>99</td>
<td>other</td>
</tr>
</tbody>
</table>

Flash movie cast members have the following possible `getError` values:

- `FALSE`—No error occurred.
- `#memory`—There is not enough memory to load the cast member.
- `#fileNotFound`—The file containing the cast member's assets could not be found.
- `#network`—A network error prevented the cast member from loading.
- `#fileFormat`—The file was found, but it appears to be of the wrong type, or an error occurred while reading the file.
- `#other`—Some other error occurred.

When an error occurs as a cast member streams into memory, Director sets the cast member’s state property to -1. Use the `getError` function to determine what type of error occurred.
Parameters
None.

Example
This handler uses `getError` to determine whether an error involving the Shockwave Audio cast member Norma Desmond Speaks occurred and displays the appropriate error string in a field if it did:

```-- Lingo syntax
on exitFrame
  if member("Norma Desmond Speaks").getError() <> 0 then
    member("Display Error Name").text = member("Norma Desmond Speaks").getErrorString()
  end if
end
```

```// JavaScript syntax
function exitFrame() {
  var memNor = member("Norma Desmond Speaks").getError();
  if (memNor != 0) {
    member("Display Error Name").text = member("Norma Desmond Speaks").getErrorString();
  }
}
```

The following handler checks to see whether an error occurred for a Flash cast member named Dali, which was streaming into memory. If an error occurred, and it was a memory error, the script uses the `unloadCast` command to try to free some memory; it then branches the playhead to a frame in the Director movie named Artists, where the Flash movie sprite first appears, so Director can again try to load and play the Flash movie. If something other than an out-of-memory error occurred, the script goes to a frame named Sorry, which explains that the requested Flash movie can't be played.

```-- Lingo syntax
on CheckFlashStatus
  errorCheck = member("Dali").getError()
  if errorCheck <> 0 then
    if errorCheck = #memory then
      member("Dali").clearError()
      unloadCast()
      _movie.go("Artists")
    else
      _movie.go("Sorry")
    end if
  end if
end
```
// JavaScript syntax
function CheckFlashStatus() {
    var errorCheck = member("Dali").getError();
    if (errorCheck != 0) {
        if (errorCheck == "memory") {
            member("Dali").clearError();
            unloadCast();
            _movie.go("Artists");
        } else {
            _movie.go("Sorry");
        }
    }
}

See also

clearError(), getErrorString(), state (Flash, SWA)

**getError()** (XML)

**Usage**

`parserObject.getError()`

**Description**

Function; returns the descriptive error string associated with a given error number (including the line and column number of the XML where the error occurred). When there is no error, this function returns `<VOID>`.

**Parameters**

None.

**Example**

These statements check an error after parsing a string containing XML data:

```lingo
errCode = parserObj.parseString(member("XMLtext").text)
errorString = parserObj.getError()
if voidP(errorString) then
    -- Go ahead and use the XML in some way
else
    alert "Sorry, there was an error " & errorString
    -- Exit from the handler
    exit
end if
```

**getErrorString()**

**Usage**

-- Lingo syntax
`memberObjRef.getErrorString()`

// JavaScript syntax
`memberObjRef.getErrorString();`

**Description**

Function; for Shockwave Audio (SWA) cast members, returns the error message string that corresponds to the error value returned by the `getError()` function.
Possible `getError()` integer values and corresponding `getErrorString()` messages are:

<table>
<thead>
<tr>
<th><code>getError()</code> value</th>
<th><code>getErrorString()</code> message</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>OK</td>
</tr>
<tr>
<td>1</td>
<td>memory</td>
</tr>
<tr>
<td>2</td>
<td>network</td>
</tr>
<tr>
<td>3</td>
<td>playback device</td>
</tr>
<tr>
<td>99</td>
<td>other</td>
</tr>
</tbody>
</table>

**Parameters**

None.

**Example**

This handler uses `getError()` to determine whether an error occurred for Shockwave Audio cast member Norma Desmond Speaks, and if so, uses `getErrorString` to obtain the error message and assign it to a field cast member:

```lingo
-- Lingo syntax
on exitFrame
  if member("Norma Desmond Speaks").getError() <> 0 then
    member("Display Error Name").text = member("Norma Desmond Speaks").getErrorString()
  end if
end
```

```javascript
// JavaScript syntax
function exitFrame() {
  var memNor = member("Norma Desmond Speaks").getError();
  if (memNor !== 0) {
    member("Display Error Name").text = member("Norma Desmond Speaks").getErrorString();
  }
}
```

**See also**

`getError()` (Flash, SWA)

**getFinderInfo()**

**Usage**

```lingo
-- Lingo syntax
fileioObjRef.getFinderInfo()
```

```javascript
// JavaScript syntax
fileioObjRef.getFinderInfo();
```

**Description**

Fileio method (Macintosh only); Returns the finder information for an open file.

You must first open a file by calling `openFile()` before using `getFinderInfo()` to return the file's finder information.
Parameters
None.

See also
Fileio, openFile()

getFlashProperty()

Usage

-- Lingo syntax
spriteObjRef.getFlashProperty(targetName, symProp)

// JavaScript syntax
spriteObjRef.getFlashProperty(targetName, symProp);

Description
This function allows Lingo to invoke the Flash action script function \texttt{getProperty()} on the
given Flash sprite. This Flash action script function is used to get the value of properties of movie
clips or levels within a Flash movie. This is similar to testing sprite properties within Director.

To get a global property of the Flash sprite, pass an empty string as the \texttt{targetName}. These global
Flash properties can be tested: \#focusRect and \#spriteSoundBufferTime.

See the Flash documentation for descriptions of these properties.

Parameters
\begin{itemize}
  \item \texttt{targetName} Required. A string that specifies the name of the movie clip or level whose property
        you want to get within the given Flash sprite.
  \item \texttt{symProp} Required. A symbol that specifies the name of the property to get. Valid values include:
        \#posX, \#posY, \#scaleX, \#scaleY, \#visible, \#rotate, \#alpha, \#name, \#width, \#height,
        \#target, \#url, \#dropTarget, \#totalFrames, \#currentFrame, \#cursor, and \#lastFrameLoaded.
\end{itemize}

Example
This statement gets the value of the \#rotate property of the movie clip Star in the Flash member
in sprite 3:

-- Lingo syntax
sprite(3).setFlashProperty("Star", \#rotate)
sprite(3).getFlashProperty()

// JavaScript syntax
sprite(3).setFlashProperty("Star", symbol("rotate"));
sprite(3).getFlashProperty();
getFrameLabel()

Usage
sprite(whichFlashSprite).getFrameLabel(whichFlashFrameNumber)
gFrameLabel(sprite whichFlashSprite, whichFlashFrameNumber)

Description
Function; returns the frame label within a Flash movie that is associated with the frame number requested. If the label doesn’t exist, or that portion of the Flash movie has not yet been streamed in, this function returns an empty string.

Parameters

whichFlashFrameNumber Required. Specifies the frame number that is associated with the frame label.

Example
The following handler looks to see if the marker on frame 15 of the Flash movie playing in sprite 1 is called "Lions". If it is, the Director movie navigates to frame "Lions". If it isn’t, the Director movie stays in the current frame and the Flash movie continues to play.

-- Lingo syntax
on exitFrame
  if sprite(1).getFrameLabel(15) = "Lions" then
    go "Lions"
  else
    go the frame
  end if
end

// JavaScript syntax
function exitFrame() {
  if (sprite(1).getFrameLabel(15) == "Lions") {
    _movie.go("Lions");
  } else {
    _movie.go(_movie.frame);
  }
}

getHardwareInfo()

Usage
getRendererServices().getHardwareInfo()

Description
3D rendererServices method; returns a property list with information about the user’s video card. The list contains the following properties:
#present is a Boolean value indicating whether the computer has hardware video acceleration.
#vendor indicates the name of the manufacturer of the video card.
#model indicates the model name of the video card.
#version indicates the version of the video driver.
#maxTextureSize is a linear list containing the maximum width and height of a texture, in pixels. Textures that exceed this size are downsampled until they do not. To avoid texture sampling artifacts, author textures of various sizes and choose the ones that do not exceed the #maxTextureSize value at run time.

#supportedTextureRenderFormats is a linear list of texture pixel formats supported by the video card. For details, see textureRenderFormat.

#textureUnits indicates the number of texture units available to the card.

#depthBufferRange is a linear list of bit-depth resolutions to which the depthBufferDepth property can be set.

#colorBufferRange is a linear list of bit-depth resolutions to which the colorBufferDepth property can be set.

Example

This statement displays a detailed property list of information about the user's hardware:

```lingo
put getRendererServices().getHardwareInfo() -- [present: 1, vendor: "NVIDIA Corporation", model: "32MB DDR NVIDIA GeForce2 GTS (Dell)", version: "4.12.01.0532", maxTextureSize: [2048, 2048], supportedTextureRenderFormats: [rgba8888, rgba8880, rgba5650, rgba5551, rgba5550, rgba4444], textureUnits: 2, depthBufferRange: [16, 24], colorBufferRange: [16, 32]]
```

See also

getRendererServices()

getHotSpotRect()

Usage

-- Lingo syntax
spriteObjRef.getHotSpotRect(hotSpotID)

// JavaScript syntax
spriteObjRef.getHotSpotRect(hotSpotID);

Description

QuickTime VR function; returns an approximate bounding rectangle for a hot spot. If the hot spot doesn't exist or isn't visible on the Stage, this function returns rect(0, 0, 0, 0). If the hot spot is partially visible, this function returns the bounding rectangle for the visible portion.

Parameters

**hotSpotID** Required. Specified the hot spot from which a bounding rectangle is returned.
getLast()

Usage
list.getLast()
getLast(/list)

Description
List function; identifies the last value in a linear or property list specified by list.

Parameters
None.

Example
This statement identifies the last item, 22, in the list Answers, which consists of [10, 12, 15, 22]:
put Answers.getLast()

This statement identifies the last item, 850, in the list Bids, which consists of [#Gee:750, #Kayne:600, #Ohashi:850]:
put Bids.getLast()

gLatestNetID

Usage
gLatestNetID

Description
This function returns an identifier for the last network operation that started. The identifier returned by getLatestNetID can be used as a parameter in the netDone, netError, and netAbort functions to identify the last network operation.

Note: This function is included for backward compatibility. It is recommended that you use the network ID returned from a net lingo function rather than getLatestNetID. However, if you use getLatestNetID, use it immediately after issuing the netLingo command.

Parameters
None.

Example
This script assigns the network ID of a getNetText operation to the field cast member Result so results of that operation can be accessed later:
on startOperation
global gNetID
getNetText("url")
set gNetID = getLatestNetID()
end

on checkOperation
global gNetID
if netDone(gNetID) then
  put netTextResult into member "Result"
end if
end

See also
netAbort, netDone(), netError()
getUserText()

Usage

-- Lingo syntax
fileioObjRef.getLength()

// JavaScript syntax
fileioObjRef.getLength();

Description

Fileio method; Returns the length of an open file.

You must first open a file by calling openFile() before using getLength() to return the length of the file.

Parameters

None.

See also

Fileio, openFile()

getUserText()

Usage

getUserText(URL {, serverOSString} {, characterSet})

Description

Function; starts the retrieval of text from a file usually on an HTTP or FTP server, or initiates a CGI query.

The first syntax shown starts the text retrieval. You can submit HTTP CGI queries this way and must properly encode them in the URL. The second syntax includes a property list and submits a CGI query, providing the proper URL encoding.

Use the optional parameter propertyList to take a property list for CGI queries. The property list is URL encoded and the URL sent is (urlstring & "?" & encodedproplist).

Use the optional parameter serverOSString to encode any return characters in propertyList. The value defaults to UNIX but may be set to Win or Mac and translates any carriage returns in the propertyList argument into those used on the server. For most applications, this setting is unnecessary because line breaks are usually not used in form responses.

The optional parameter characterSet applies only if the user is running Director on a shift-JIS (Japanese) system. Possible character set settings are JIS, EUC, ASCII, and AUTO. Lingo converts the retrieved data from shift-JIS to the named character set. Using the AUTO setting, character set tries to determine what character set the retrieved text is in and translate it to the character set on the local machine. The default setting is ASCII.

Use netDone to find out when the getUserText operation is complete, and netError to find out if the operation was successful. Use netTextResult to return the text retrieved by getUserText.

The function works with relative URLs.
To see an example of `getNetText()` used in a completed movie, see the Forms and Post movie in the Learning/Lingo folder inside the Director application folder.

**Parameters**

- **URL** Required. The URL to the file that contains the text to get.
- **propertyList** Optional. Specifies a property list used for CGI queries.
- **serverOSString** Optional. Specifies the encoding of return characters in `propertyList`.
- **characterSet** Optional. Specifies character settings.

**Example**

This script retrieves text from the URL `http://BigServer.com/sample.txt` and updates the field cast member the mouse pointer is on when the mouse button is clicked:

```lingo
property spriteNum
property theNetID

on mouseUp me
  theNetID = getNetText("http://BigServer.com/sample.txt")
end

on exitFrame me
  if netDone(theNetID) then
    sprite(spriteNum).member.text = netTextResult(theNetID)
  end if
end
```

This example retrieves the results of a CGI query:

```lingo
getNetText("http://www.yourserver.com/cgi-bin/query.cgi?name=Bill")
```

This is the same as the previous example, but it uses a property list to submit a CGI query, and does the URL encoding for you:

```lingo
getNetText("http://www.yourserver.com/cgi-bin/query.cgi". [#name:"Bill"])
```

See also

- `netDone()`, `netError()`, `netTextResult()`

### getNormalized

**Usage**

```lingo
getNormalized(vector)
vector.getNormalized()
```

**Description**

3D vector method; copies the vector and divides the x, y, and z components of the copy by the length of the original vector. The resulting vector has a length of 1 world unit.

This method returns the copy and leaves the original vector unchanged. To normalize the original vector, use the `normalize` command.
Example

The following statement stores the normalized value of the vector MyVec in the variable Norm. The value of Norm is vector (-0.1199, 0.9928, 0.0000) and the magnitude of Norm is 1.

```
MyVec = vector(-209.9019, 1737.5126, 0.0000)
Norm = MyVec.getNormalized()
put Norm
  -- vector( -0.1199, 0.9928, 0.0000 )
put Norm.magnitude
  -- 1.0000
```

See also

normalize

getNthFileNameInFolder()

Usage

```
getNthFileNameInFolder(folderPath, fileNumber)
```

Description

Movie method; returns a filename from the directory folder based on the specified path and number within the folder. To be found by the `getNthFileNameInFolder` function, Director movies must be set to visible in the folder structure. (On the Macintosh, other types of files are found whether they are visible or invisible.) If this function returns an empty string, you have specified a number greater than the number of files in the folder.

The `getNthFileNameInFolder` function doesn't work with URLs.

To specify other folder names, use the `@ pathname` operator or the full path defined in the format for the specific platform on which the movie is running. For example:

- In Windows, use a directory path such as C:/Director/Movies.
- On the Macintosh, use a pathname such as HardDisk:Director:Movies. To look for files on the Macintosh desktop, use the path HardDisk:Desktop Folder
- This function is not available in Shockwave Player.

Parameters

- `folderPath` Required. Specifies the path to the folder that contains the file.
- `fileNumber` Required. Specifies the index position of the file in the folder.

Example

The following handler returns a list of filenames in the folder on the current path. To call the function, use parentheses, as in `put currentFolder()`.

```
on currentFolder
  fileList = [ ]
  repeat with i = 1 to 100
    n = getNthFileNameInFolder(the moviePath, i)
    if n = EMPTY then exit repeat
    fileList.append(n)
  end repeat
  return fileList
end currentFolder
```

See also

```
@ (pathname), Movie
```

---

getNthFileNameInFolder()  337
getOne()

Usage

```
list.getOne(value)
gOne(list, value)
```

Description

List function; identifies the position (linear list) or property (property list) associated with a value in a list.

For values contained in the list more than once, only the first occurrence is displayed. The `getOne` command returns the result 0 when the specified value is not in the list.

When used with linear lists, the `getOne` command performs the same functions as the `getPos` command.

Parameters

- `value` Required. Specifies the value associated with the position or property.

Example

This statement identifies the position of the value 12 in the linear list `Answers`, which consists of `[10, 12, 15, 22]`:

```
put Answers.getOne(12)
```

The result is 2, because 12 is the second value in the list.

This statement identifies the property associated with the value 12 in the property list `Answers`, which consists of `[#a:10, #b:12, #c:15, #d:22]`:

```
put Answers.getOne(12)
```

The result is `#b`, which is the property associated with the value 12.

See also

- `getPos()`

getOSDirectory()

Usage

```
-- Lingo syntax
fileioObjRef.getOSDirectory()

// JavaScript syntax
fileioObjRef.getOSDirectory();
```

Description

Fileio method; Returns the full path to the System folder (Macintosh) or Windows directory (Windows).

Parameters

None.

See also

- `Fileio`
getPixel()

Usage

-- Lingo syntax
imageObjRef.getPixel(x, y {, #integer})
imageObjRef.getPixel(point(x, y) {, #integer})

// JavaScript syntax
imageObjRef.getPixel(x, y {, #integer});
imageObjRef.getPixel(point(x, y) {, #integer});

Description

Image method. Returns an indexed or RGB color of the pixel at a specified point in a given image.

The index of the rows and columns of the returned image starts with 0. Therefore, in order to access the top left pixel of an image, specify the location as (0,0), and not (1,1). If a given image is h pixels high and w pixels wide, to access the bottom right pixel of the image, specify the location as (w,1), (h,1).

This method returns a value of 0 if the specified pixel is outside the given image.

To set a lot of pixels to the color of another pixel, it is faster to set them as raw numbers (by using the optional #integer parameter). Raw integer color values are also useful because they contain alpha layer information as well as color when the image is 32-bit. The alpha channel information can be extracted from the raw integer by dividing the integer by 2^8+8+8.

Parameters

x Required if specifying a pixel using x and y coordinates. An integer that specifies the x coordinate of the pixel.
y Required if specifying a pixel using x and y coordinates. An integer that specifies the y coordinate of the pixel.
#integer Optional. A symbol that specifies the raw number of the returned color value.
point(x, y) Required if specifying a pixel using a point. A point that specifies the point of the pixel.

Example

These statements get the color of the pixel at point (90, 20) in member Happy and set sprite 2 to that color:

This statement sets the variable alpha to the alpha channel value of the point (25, 33) in the 32-bit image object myImage:

See also

color(), image(), power(), setPixel()
getPlayList()

Usage

-- Lingo syntax
soundChannelObjRef.getPlayList()

// JavaScript syntax
soundChannelObjRef.getPlayList();

Description

Sound Channel method; returns a copy of the list of queued sounds for a sound channel.

The returned list does not include the currently playing sound, nor may it be edited directly. You must use setPlayList().

The playlist is a linear list of property lists. Each property list corresponds to one queued sound cast member. Each queued sound may specify these properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#member</td>
<td>The sound cast member to queue. This property must be provided; all others are optional.</td>
</tr>
<tr>
<td>#startTime</td>
<td>The time within the sound at which playback begins, in milliseconds. The default is the beginning of the sound. See startTime.</td>
</tr>
<tr>
<td>#endTime</td>
<td>The time within the sound at which playback ends, in milliseconds. The default is the end of the sound. See endTime.</td>
</tr>
<tr>
<td>#loopCount</td>
<td>The number of times to play a loop defined with #loopStart time and #loopEnd time. The default is 1. See loopCount.</td>
</tr>
<tr>
<td>#loopStart time</td>
<td>The time within the sound to begin a loop, in milliseconds. See loopStart time.</td>
</tr>
<tr>
<td>#loopEnd time</td>
<td>The time within the sound to end a loop, in milliseconds. See loopEnd time.</td>
</tr>
<tr>
<td>#preloadTime</td>
<td>The amount of the sound to buffer before playback, in milliseconds. See preloadTime.</td>
</tr>
</tbody>
</table>

Parameters

None.

Example

The following handler queues two sounds in sound channel 2, starts playing them, and then displays the playList in the message window. The playlist includes only the second sound queued, because the first sound is already playing.

-- Lingo syntax
on playMusic
    sound(2).queue(member("Chimes"))
    sound(2).queue([#member:member("introMusic").member("introMusic"), #startTime:3000, #endTime:10000, #loopCount:5, #loopStart time:8000, #loopEnd time:8900])
    put(sound(2).getPlayList())
    sound(2).play()
end playMusic
// JavaScript syntax
function playMusic() {
    sound(2).queue(member("Chimes"));
    sound(2).queue(propList("member",member("introMusic"), "startTime",3000, "endTime",10000, "loopCount",5, "loopStartTime",8000, "loopEndTime",8900));
    put(sound(2).getPlayList());
    sound(2).play();
}

See also
eendTime, loopCount, loopEndTime, loopStartTime, Member, member, preLoadTime, queue(), setPlayList(), Sound Channel, startTime

gGetPosition()

Usage
-- Lingo syntax
fileioObjRef.getPosition()

// JavaScript syntax
fileioObjRef.getPosition();

Description
Fileio method; Returns the position of a file.

Parameters
None.

See also
Fileio

ggetPref()

Usage
-- Lingo syntax
_player.getPref(stringPrefName)

// JavaScript syntax
_player.getPref(stringPrefName);

Description
Player method; retrieves the content of the specified file.

When you use this method, replace stringPrefName with the name of a file created by
the setPref() method. If no such file exists, getPref() returns VOID (Lingo) or null
(JavaScript syntax).

The filename used for stringPrefName must be a valid filename only, not a full path; Director
supplies the path. The path to the file is handled by Director. The only valid file extensions for
stringPrefName are .txt and .htm; any other extension is rejected.

Do not use this method to access read-only or locked media.

Note: In a browser, data written by setPref() is not private. Any movie with Shockwave content can
read this information and upload it to a server. Confidential information should not be stored using
setPref().

getPref() 341
To see an example of `getPref()` used in a completed movie, see the Read and Write Text movie in the Learning/Lingo folder inside the Director application folder.

**Parameters**

`stringPrefName` Required. A string that specifies the file for which content is retrieved.

**Example**

This handler retrieves the content of the file Test and then assigns the file’s text to the field Total Score:

```-- Lingo syntax
on mouseUp
    theText = _player.getPref("Test")
    member("Total Score").text = theText
end

// JavaScript syntax
function mouseUp() {
    var theText = _player.getPref("Test");
    member("Total Score").text = theText;
}
```

See also

`Player`, `setPref()`

**getPos()**

**Usage**

```list.getPos(value)
getPos(list, value)```

**Description**

List function; identifies the position of a value in a list. When the specified value is not in the list, the `getPos` command returns the value 0.

For values contained in the list more than once, only the first occurrence is displayed. This command performs the same function as the `getOne` command when used for linear lists.

**Parameters**

`value` Required. Specifies the value associated with the position.

**Example**

This statement identifies the position of the value 12 in the list Answers, which consists of `[#a:10, #b:12, #c:15, #d:22]`:

```put Answers.getPos(12)
The result is 2, because 12 is the second value in the list.
```

See also

`getOne()`
getPref()

Usage

getPref(prefFileName)

Description

Function; retrieves the content of the specified file.

When you use this function, replace prefFileName with the name of a file created by the setPref function. If no such file exists, getPref returns VOID.

The filename used for prefFileName must be a valid filename only, not a full path; Director supplies the path. The path to the file is handled by Director. The only valid file extensions for prefFileName are .txt and .htm; any other extension is rejected.

Do not use this command to access read-only or locked media.

Note: In a browser, data written by setPref is not private. Any movie with Shockwave content can read this information and upload it to a server. Confidential information should not be stored using setPref.

To see an example of getPref() used in a completed movie, see the Read and Write Text movie in the Learning/Lingo folder inside the Director application folder.

Parameters

prefFileName Required. Specifies the file from which content is retrieved.

Example

This handler retrieves the content of the file Test and then assigns the file's text to the field Total Score:

```lingo
on mouseUp
  theText = getPref("Test")
  member("Total Score").text = theText
end```

See also

setPref()

getProp()

Usage

getProp(list, property)

list.property

Description

Property list function; identifies the value associated with a property in a property list.

Almost identical to the getaProp command, the getProp command displays an error message if the specified property is not in the list or if you specify a linear list.

Parameters

list Required. Specifies the property list from which property is retrieved.

property Required. Specifies the property with which the identified value is associated.
Example

This statement identifies the value associated with the property #c in the property list Answers, which consists of [#a:10, #b:12, #c:15, #d:22]:

getProp(Answers, #c)

The result is 15, because 15 is the value associated with #c.

See also

getOne()

getPropAt()

Usage

list.getPropAt(index)
getPropAt(9st, index)

Description

Property list function; for property lists only, identifies the property name associated with a specified position in a property list. If the specified item isn't in the list, or if you use getPropAt() with a linear list, a script error occurs.

Parameters

index Required. Specifies the index position of the property in the property list.

Example

This statement displays the second property in the given list:

put Answers.getPropAt(2)
-- #b

The result is 20, which is the value associated with #b.

getRendererServices()

Usage

getRendererServices() getRendererServices().whichGetRendererServicesProperty

Description

3D command; returns the rendererServices object. This object contains hardware information and properties that affect all 3D sprites and cast members.

The rendererServices object has the following properties:

• renderer indicates the software rasterizer used to render all 3D sprites.
• rendererDeviceList returns a list of software rasterizers available on the user's system. Possible values include #openGL, #directX5_2, #directX7_0, and #software. The value of renderer must be one of these. This property can be tested but not set.
• textureRenderFormat indicates the pixel format used by the renderer. Possible values include #rgba8888, #rgba8880, #rgba5650, #rgba5550, #rgba5551, and #rgba4444. The four digits in each symbol indicate how many bits are used for each red, green, blue, and alpha component.
• depthBufferDepth indicates the bit depth of the hardware output buffer.
• colorBufferDepth indicates the bit depth of the color buffer. This property can be tested but not set.
• modifiers is a linear list of modifiers available for use by models in 3D cast members. Possible values include #collision, #bonesPlayer, #keyframePlayer, #toon, #lod, #meshDeform, #sds, #inker, and third-party Xtra-based modifiers. This property can be tested but not set.
• primitives is a linear list of primitive types available for use in the creation of new model resources. Possible values include #sphere, #box, #cylinder, #plane, #particle, and third-party Xtra-based primitive types. This property can be tested but not set.

Note: For more detailed information about these properties, see the individual property entries.

Parameters
None.

See also
renderer, preferred3dRenderer, active3dRenderer, rendererDeviceList

getStreamStatus()

Usage
getStreamStatus(netID)
getStreamStatus(URLString)

Description
Function; returns a property list matching the format used for the globally available tellStreamStatus function that can be used with callbacks to sprites or objects. The list contains the following strings:

- #URL String containing the URL location used to start the network operation.
- #state String consisting of Connecting, Started, InProgress, Complete, "Error", or "NoInformation" (this last string is for the condition when either the net ID is so old that the status information has been dropped or the URL specified in URLString was not found in the cache).
- #bytesSoFar Number of bytes retrieved from the network so far.
- #bytesTotal Total number of bytes in the stream, if known. The value may be 0 if the HTTP server does not include the content length in the MIME header.
- #error String containing "" (EMPTY) if the download is not complete, OK if it completed successfully, or an error code if the download ended with an error.

For example, you can start a network operation with getNetText() and track its progress with getStreamStatus().

Parameters

netID Required. A network operation that represents the stream of text to operate on.
Example

This statement displays in the message window the current status of a download begun with getNetText() and the resulting net ID placed in the variable netID:

```lingo
put getStreamStatus(netID)
```

```
-- [URL: "www.macromedia.com", #state: "InProgress", #bytesSoFar: 250, 
#bytesTotal: 50000, #error: EMPTY]
```

See also

on streamStatus, tellStreamStatus()

getVariable()

Usage

```lingo
spriteObjRef.getVariable(variableName {, returnValueOrReference})
```

// JavaScript syntax
```javascript
spriteObjRef.getVariable(variableName {, returnValueOrReference});
```

Description

Function; returns the current value of the given variable from the specified Flash sprite. Flash variables were introduced in Flash version 4.

This function can be used in two ways.

Setting the optional returnValueOrReference parameter to TRUE (the default) returns the current value of the variable as a string. Setting the returnValueOrReference parameter to FALSE returns the current literal value of the Flash variable.

If the value of the Flash variable is an object reference, you must set the returnValueOrReference parameter to FALSE in order for the returned value to have meaning as an object reference. If it is returned as a string, the string will not be a valid object reference.

Parameters

variableName Required. Specifies the name of the variable whose value is returned.

returnValueOrReference Optional. Specifies whether the returned value is a string (TRUE) or as an object reference (FALSE).

Example

This statement sets the variable tValue to the string value of the Flash variable named gOtherVar in the Flash movie in sprite 3:

```lingo
tValue = sprite(3).getVariable("gOtherVar", TRUE)
```

```
put(tValue) --- "5"
```

// JavaScript syntax
```javascript
var tValue = sprite(3).getVariable("gOtherVar", true);
```

```
trace(tValue); // 5
```
This statement sets the variable \texttt{tObject} to refer to the same object that the variable named \texttt{gVar} refers to in the Flash movie in sprite 3:

\begin{verbatim}
-- Lingo syntax
tObject = sprite(3).getVariable("gVar",FALSE)
// JavaScript syntax
var tObject = sprite(3).getVariable("gVar",0);
\end{verbatim}

This statement returns the value of the variable \texttt{currentURL} from the Flash cast member in sprite 3 and displays it in the Message window:

\begin{verbatim}
-- Lingo syntax
put(sprite(3).getVariable("currentURL"))
// JavaScript syntax
trace(sprite(3).getVariable("currentURL"));
\end{verbatim}

\textbf{See also}

\texttt{setVariable()}

\section*{getWorldTransform()}

\subsection*{Usage}

\begin{verbatim}
member\texttt{(whichCastmember).node\texttt{(whichNode).getWorldTransform()}}
member\texttt{(whichCastmember).node\texttt{(whichNode).getWorldTransform().\position}}
member\texttt{(whichCastmember).node\texttt{(whichNode).getWorldTransform().\rotation}}
member\texttt{(whichCastmember).node\texttt{(whichNode).getWorldTransform().\scale}}
\end{verbatim}

\subsection*{Description}

3D command; returns the world-relative transform of the model, group, camera, or light represented by \texttt{node}.

The \texttt{transform} property of a node is calculated relative to the transform of the node’s parent, and is therefore parent-relative. The \texttt{getWorldTransform()} command calculates the node’s transform relative to the origin of the 3D world, and is therefore world-relative.

Use \texttt{member\texttt{(whichCastmember).node\texttt{(whichNode).getWorldTransform().\position}} to find the position property of the node’s world-relative transform. You can also use \texttt{worldPosition} as a shortcut for \texttt{getWorldTransform().\position}.

Use \texttt{member\texttt{(whichCastmember).node\texttt{(whichNode).getWorldTransform().\rotation}} to find the rotation property of the node’s world-relative transform.

Use \texttt{member\texttt{(whichCastmember).node\texttt{(whichNode).getWorldTransform().\scale}} to find the scale property of the node’s world-relative transform.

These properties can be tested but not set.
Example

This statement shows the world-relative transform of the model named Box, followed by its position and rotation properties:

```
put member("3d world").model("Box").getWorldTransform()
-- transform(1.000000,0.000000,0.000000,0.000000, \
0.000000,1.000000,0.000000,0.000000, \
0.000000,0.000000,1.000000,0.000000, - \
94.144844,119.012825,0.000000,1.000000)
```

```
put member("3d world").model("Box").getWorldTransform().position
-- vector(-94.1448, 119.0128, 0.0000)
```

```
put member("3d world").model("Box").getWorldTransform().rotation
-- vector(0.0000, 0.0000, 0.0000)
```

See also

worldPosition, transform (property)

**go()**

Usage

-- Lingo syntax
_movie.go(frameNameOrNum [, movieName])

// JavaScript syntax
_movie.go(frameNameOrNum [, movieName]);

Description

Movie method; causes the playhead to branch to a specified frame in a specified movie.

This method can be used to tell the playhead to loop to the previous marker, and is a convenient means of keeping the playhead in the same section of the movie while script remains active.

It is best to use marker labels for `frameNameOrNum` instead of frame numbers; editing a movie can cause frame numbers to change. Using marker labels also makes it easier to read scripts.

Calling `go()` with the `movieName` parameter loads frame 1 of the movie. If `go()` is called from within a handler, the handler in which it is placed continues executing. To suspend the handler while playing the movie, use the `play()` method, which may be followed by a subsequent call to `playDone()` to return.

When you specify a movie to play, specify its path if the movie is in a different folder, but to prevent a potential load failure, don’t include the movie’s .dir, .dxr, or .dcr file extension.

To more efficiently go to a movie at a URL, use the `downloadNetThing()` method to download the movie file to a local disk first, and then use the `go()` method with the `movieName` parameter to go to that movie on the local disk.

The `goLoop()` method sends the playhead to the previous marker in a movie, which is a convenient means of keeping the playhead in the same section of the movie while Lingo or JavaScript syntax remains active.

The following are reset when a movie is loaded: `beepOn` and `constraint` properties; `keyDownScript`, `mouseDownScript`, and `mouseUpScript`; `cursor` and `immediate sprite` properties; `cursor()` and `puppetSprite()` methods; and custom menus. However, the `timeoutScript` is not reset when loading a movie.
Parameters

-frameNameOrNum Required. A string that specifies the marker label of the frame to which the playhead branches, or an integer that specifies the number of the frame to which the playhead branches.

-movieName Optional. A string that specifies the movie that contains the frame specified by frameNameOrNum. This value must specify a movie file; if the movie is in another folder, movieName must also specify the path.

Example

This statement sends the playhead to the marker named start:

-- Lingo syntax
_movie.go("start")

// JavaScript syntax
_movie.go("start");

This statement sends the playhead to the marker named Memory in the movie named Noh Tale to Tell:

-- Lingo syntax
_movie.go("Memory", "Noh Tale to Tell")

// JavaScript syntax
_movie.go("Memory", "Noh Tale to Tell");

The following handler tells the movie to loop in the current frame. This handler is useful for making the movie wait in a frame while it plays so the movie can respond to events.

-- Lingo syntax
on exitFrame
_movie.go(_movie.frame)
end

// JavaScript syntax
function exitFrame() {  
_movie.go(_movie.frame); 
}

See also
downloadNetThing, goLoop(), Movie

goLoop()

Usage

-- Lingo syntax
_movie.goLoop()

// JavaScript syntax
_movie.goLoop();

Description

Movie method; sends the playhead to the previous marker in the movie, either one marker back from the current frame if the current frame does not have a marker, or to the current frame if the current frame has a marker.
If no markers are to the left of the playhead, the playhead branches to:

- The next marker to the right if the current frame does not have a marker.
- The current frame if the current frame has a marker.
- Frame 1 if the movie contains no markers.

**Parameters**

None.

**Example**

This statement causes the movie to loop between the current frame and the previous marker:

```
-- Lingo syntax
_movie.goLoop()

// JavaScript syntax
_movie.goLoop();
```

**See also**

`go()`, `goNext()`, `goPrevious()`, `Movie`

---

**goNext()**

**Usage**

```
-- Lingo syntax
_movie.goNext()

// JavaScript syntax
_movie.goNext();
```

**Description**

Movie method; sends the playhead to the next marker in the movie.

If no markers are to the right of the playhead, the playhead goes to the last marker in the movie or to frame 1 if there are no markers in the movie.

**Parameters**

None.

**Example**

This statement sends the playhead to the next marker in the movie:

```
-- Lingo syntax
_movie.goNext()

// JavaScript syntax
_movie.goNext();
```

**See also**

`go()`, `goLoop()`, `goPrevious()`, `Movie`
goPrevious()

Usage
-- Lingo syntax
_movie.goPrevious()

// JavaScript syntax
_movie.goPrevious();

Description
Movie method; sends the playhead to the previous marker in the movie.
This marker is two markers back from the current frame if the current frame does not have a
marker or one marker back from the current frame if the current frame has a marker.
If no markers are to the left of the playhead, the playhead branches to one of the following:
• The next marker to the right if the current frame does not have a marker
• The current frame if the current frame has a marker
• Frame 1 if the movie contains no markers

Parameters
None.

Example
This statement sends the playhead to the previous marker in the movie:
-- Lingo syntax
_movie.goPrevious()

// JavaScript syntax
_movie.goPrevious();

See also
go(), goLoop(), goNext(), Movie

goToFrame()

Usage
-- Lingo syntax
spriteObjRef.goToFrame(frameNameOrNum)

// JavaScript syntax
spriteObjRef.goToFrame(frameNameOrNum);

Description
Command; plays a Flash movie sprite beginning at the frame identified by the frameNumber
parameter. You can identify the frame by either an integer indicating a frame number or by a
string indicating a label name. Using the goToFrame command has the same effect as setting a
Flash movie sprite's frame property.
Example

The following handler branches to different points within a Flash movie in channel 5. It accepts a parameter that indicates which frame to go to.

```
-- Lingo syntax
on Navigate(whereTo)
    sprite(5).goToFrame(whereTo)
end

// JavaScript syntax
function Navigate(whereTo) {
    sprite(5).goToFrame(whereTo);
}
```

gotoNetMovie

Usage

gotoNetMovie URL
gotoNetMovie (URL)

Description

Command; retrieves and plays a new movie with Shockwave content from an HTTP or FTP server. The current movie continues to run until the new movie is available.

Only URLs are supported as valid parameters. The URL can specify either a filename or a marker within a movie. Relative URLs work if the movie is on an Internet server, but you must include the extension with the filename.

When performing testing on a local disk or network, media must be located in a directory named dswmedia.

If a gotoNetMovie operation is in progress and you issue a second gotoNetMovie command before the first is finished, the second command cancels the first.

Parameters

URL Required. Specifies the URL of the Shockwave content to play.

Example

In this statement, the URL indicates a Director filename:

gotoNetMovie "http://www.yourserver.com/movies/movie1.dcr"

In this statement, the URL indicates a marker within a filename:

gotoNetMovie "http://www.yourserver.com/movies/buttons.dcr#Contents"

In the following statement, gotoNetMovie is used as a function. The function returns the network ID for the operation.

```
myNetID = gotoNetMovie ("http://www.yourserver.com/movies/
    buttons.dcr#Contents")
```
**gotoNetPage**

**Usage**

gotoNetPage "URL", {"targetName"}  

**Description**

Command; opens a movie with Shockwave content or another MIME file in the browser.

Only URLs are supported as valid parameters. Relative URLs work if the movie is on an HTTP or FTP server.

In the authoring environment, the `gotoNetPage` command launches the preferred browser if it is enabled. In projectors, this command tries to launch the preferred browser set with the Network Preferences dialog box or `browserName` command. If neither has been used to set the preferred browser, the `gotoNetPage` command attempts to find a browser on the computer.

**Parameters**

- **URL** Required. Specifies the URL of the movie with Shockwave content or MIME file to play.
- **targetName** Optional. An HTML parameter that identifies the frame or window in which the page is loaded.
  - If `targetName` is a window or frame in the browser, `gotoNetPage` replaces the contents of that window or frame.
  - If `targetName` isn’t a frame or window that is currently open, `gotoNetPage` opens a new window. Using the string "]_new" always opens a new window.
  - If `targetName` is omitted, `gotoNetPage` replaces the current page, wherever it is located.

**Example**

The following script loads the file Newpage.html into the frame or window named frwin. If a window or frame in the current window called frwin exists, that window or frame is used. If the window frwin doesn’t exist, a new window named frwin is created.

```plaintext
on keyDown
  gotoNetPage "Newpage.html", "frwin"
end
```

This handler opens a new window regardless of what window the browser currently has open:

```plaintext
on mouseUp
  goToNetPage "Todays_News.html", "]_new"
end
```

**See also**

- `browserName()`
- `netDone()`
group()

**Usage**

```plaintext
member(whichCastmember).group(whichGroup)
member(whichCastmember).group[index]
```

**Description**

3D element; a node in the 3D world that has a name, transform, parent, and children, but no other properties.

Every 3D cast member has a default group named **World** that cannot be deleted. The parent hierarchy of all models, lights, cameras, and groups that exist in the 3D world terminates in `group(“world”).`

**Example**

This statement shows that the fourth group of the cast member `newAlien` is the group `Direct01`:

```plaintext
put member(“newAlien”).group[4]
-- group(“Direct01”)
```

**See also**

`newGroup, deleteGroup, child (3D), parent`

halt()

**Usage**

```plaintext
-- Lingo syntax
_movie.halt()

// JavaScript syntax
_movie.halt();
```

**Description**

Movie method; exits the current handler and any handler that called it and stops the movie during authoring or quits the projector during runtime from a projector.

**Parameters**

None.

**Example**

This statement checks whether the amount of free memory is less than 50K and, if it is, exits all handlers that called it and then stops the movie:

```plaintext
-- Lingo syntax
if (_system.freeBytes < (50*1024)) then
_movie.halt()
end if

// JavaScript syntax
if (_system.freeBytes < (50*1024)) {
_movie.halt();
}
```

**See also**

`Movie`
handler()

Usage

scriptObject.handler(#handlerSymbol)

Description

This function returns TRUE if the given scriptObject contains a specified handler, and FALSE if it does not. The script object must be a parent script, a child object, or a behavior.

Parameters

symHandler Required. Specifies the name of the handler.

Example

This Lingo code invokes a handler on an object only if that handler exists:

if spiderObject.handler(#pounce) = TRUE then
    spiderObject.pounce()
end if

See also

handler(), new(), rawNew(), script()

handlers()

Usage

scriptObject.handlers()

Description

This function returns a linear list of the handlers in the given scriptObject. Each handler name is presented as a symbol in the list. This function is useful for debugging movies.

You cannot get the handlers of a script cast member directly. You have to get them via the script property of the member.

Parameters

None.

Example

This statement displays the list of handlers in the child object RedCar in the Message window:

put RedCar.handlers()
-- [#accelerate, #turn, #stop]

This statement displays the list of handlers in the parent script member CarParentScript in the Message window:

put member("CarParentScript").script.handlers()
-- [#accelerate, #turn, #stop]

See also

handler(), script()
hilite (command)

Usage

fieldChunkExpression.hilite()

hilite fieldChunkExpression

Description

Command; highlights (selects) in the field sprite the specified chunk, which can be any chunk that Lingo lets you define, such as a character, word, or line. On the Macintosh, the highlight color is set in the Color control panel.

Parameters

None.

Example

This statement highlights the fourth word in the field cast member Comments, which contains the string Thought for the Day:

member("Comments").word[4].hilite()

This statement causes highlighted text within the sprite for field myRecipes to be displayed without highlighting:

myLineCount = member("myRecipes").line.count
member("myRecipes").line[myLineCount + 1].hilite()

See also

char...of, item...of, line...of, word...of, delete(), mouseChar, mouseLine, mouseWord, field, selection() (function), selEnd, selStart

hitTest()

Usage

-- Lingo syntax
spriteObjRef.hitTest(point)

// JavaScript syntax
spriteObjRef.hitTest(point);

Description

Function; indicates which part of a Flash movie is directly over a specific Director Stage location. The Director Stage location is expressed as a Director point value; for example, point(100,50). The hitTest function returns these values:

• #background—The specified Stage location falls within the background of the Flash movie sprite.
• #normal—The specified Stage location falls within a filled object.
• #button—The specified Stage location falls within the active area of a button.
• #editText—The specified Stage location falls within a Flash editable text field.

Parameters

point Required. Specifies the point to test.
Example
This frame script checks to see if the mouse is currently located over a button in a Flash movie sprite in channel 5 and, if it is, the script sets a text field used to display a status message:

```
-- Lingo syntax
on exitFrame
  if sprite(5).hitTest(_mouse.mouseLoc) = #button then
    member("Message Line").text = "Click here to play the movie."
    _movie.updatestage()
  else
    member("Message Line").text = ""
  end if
  _movie.go(_movie.frame)
end

// JavaScript syntax
function exitFrame() {
  var hT = sprite(5).hitTest(_mouse.mouseLoc);
  if (hT = "button") {
    member("Message Line").text = "Click here to play the movie.";
    _movie.updatestage();
  } else {
    member("Message Line").text = "";
  }
  _movie.go(_movie.frame)
}
```

**HMStoFrames()**

**Usage**

```
HMStoFrames(hms, tempo, dropFrame, fractionalSeconds)
```

**Description**

Function; converts movies measured in hours, minutes, and seconds to the equivalent number of frames or converts a number of hours, minutes, and seconds into time if you set the *tempo* argument to 1 (1 frame = 1 second).

**Parameters**

- **hms** Required. A string expression that specifies the time in the form *sHH:MM:SS.FFD*, where:
  
  | s | A character is used if the time is less than zero, or a space if the time is greater than or equal to zero. |
  | HH | Hours. |
  | MM | Minutes. |
  | SS | Seconds. |
  | FF | Indicates a fraction of a second if *fractionalSeconds* is TRUE or frames if *fractionalSeconds* is FALSE. |
  | D | A *d* is used if *dropFrame* is TRUE, or a space if *dropFrame* is FALSE. |

- **tempo** Required. Specifies the tempo in frames per second.
dropFrame Required. Logical expression that determines whether the frame is a drop frame (TRUE) or not (FALSE). If the string hms ends in a d, the time is treated as a drop frame, regardless of the value of dropFrame.

fractionalSeconds Required. Logical expression that determines the meaning of the numbers after the seconds; they can be either fractional seconds rounded to the nearest hundredth of a second (TRUE) or the number of residual frames (FALSE).

Example

This statement determines the number of frames in a 1-minute, 30.1-second movie when the tempo is 30 frames per second. Neither the dropFrame nor fractionalSeconds arguments is used.

put HMStoFrames(" 00:01:30.10 ", 30, FALSE, FALSE)
-- 2710

This statement converts 600 seconds into minutes:

>> put framesToHMS(600, 1,0,0)
>> " 00:10:00.00 

This statement converts an hour and a half into seconds:

>> put HMStoFrames("1:30:00", 1,0,0)
>> -- 5400

See also

framesToHMS()

hold()

Usage

-- Lingo syntax
spriteObjRef.hitTest(point)

// JavaScript syntax
spriteObjRef.hitTest(point);

Description

Flash command; stops a Flash movie sprite that is playing in the current frame, but any audio continues to play.

Parameters

None.

Example

This frame script holds the Flash movie sprites playing in channels 5 through 10 while allowing the audio for these channels to continue playing:

-- Lingo syntax
on enterFrame
    repeat with i = 5 to 10
        sprite(i).hold()
    end repeat
end
// JavaScript syntax
function enterFrame() {
    var i = 5;
    while (i < 11) {
        sprite(i).hold();
        i++;
    }
}

See also
    playRate (QuickTime, AVI)

identity()

Usage
    member(whichCastmember).model(whichModel).transform.identity()
    member(whichCastmember).group(whichGroup).transform.identity()
    member(whichCastmember).camera(whichCamera).transform.identity()
    sprite(whichSprite).camera(index).transform.identity()
    member(whichCastmember).light(whichLight).transform.identity()
    transformReference.identity()

Description
    3D command; sets the transform to the identity transform, which is
    transform(1.0000,0.0000,0.0000,0.0000, 0.0000,1.0000,0.0000,0.0000,
    0.0000,0.0000,1.0000,0.0000, 0.0000,0.0000,0.0000,1.0000).
    The position property of the identity transform is vector(0, 0, 0).
    The rotation property of the identity transform is vector(0, 0, 0).
    The scale property of the identity transform is vector(1, 1, 1).
    The identity transform is parent-relative.

Parameters
    None.

Example
    This statement sets the transform of the model named Box to the identity transform:
    member("3d world").model("Box").transform.identity()

See also
    transform (property), getWorldTransform()
idleLoadDone()

Usage
-- Lingo syntax
_movie.idleLoadDone(intLoadTag)

// JavaScript syntax
_movie.idleLoadDone(intLoadTag);

Description
Movie method; reports whether all cast members with the given tag have been loaded (TRUE) or are still waiting to be loaded (FALSE).

Parameters
intLoadTag Required. An integer that specifies the load tag for the cast members to test.

Example
This statement checks whether all cast members whose load tag is 20 have been loaded and then plays the movie Kiosk if they are:

-- Lingo syntax
if (_movie.idleLoadDone(20)) then
    _movie.play(1, "Kiosk")
end if

// JavaScript syntax
if (_movie.idleLoadDone(20)) {
    _movie.play(1, "Kiosk");
}

See also
idleHandlerPeriod, idleLoadMode, idleLoadPeriod, idleLoadTag, idleReadChunkSize, Movie

ignoreWhiteSpace()

Usage
XMLparserObject.ignoreWhiteSpace(trueOrFalse)

Description
XML Command; specifies whether the parser should ignore or retain white space when generating a Lingo list. When ignoreWhiteSpace() is set to TRUE (the default), the parser ignores white space. When set to FALSE, the parser will retain white space and treat it as actual data.

If an element has separate beginning and ending tags, such as <sample> </sample>, character data within the element will be ignored if, and only if, it is composed of white space only. If there is any non-white space, or if ignoreWhiteSpace() is set to FALSE, there will be a CDATA node with the exact text, including any white space.

Parameters
trueOrFalse Required. A value that specifies whether the parser should ignore white space (TRUE) or not (FALSE).
Example

These Lingo statements leave `ignoreWhiteSpace()` set to the default of `TRUE` and parse the given XML into a list. The element `<sample>` has no children in the list.

```lingo
XMLtext = "<sample> </sample>"
parserObj.parseString(XMLtext)
theList = parserObj.makelist()
put theList
-- ['ROOT OF XML DOCUMENT': ['!ATTRIBUTES': [:], "sample": ['!ATTRIBUTES': [:]]]
```

These Lingo statements set `ignoreWhiteSpace()` to `FALSE` and then parse the given XML into a list. The element `<sample>` now has a child containing one space character.

```lingo
XMLtext = "<sample> </sample>"
gparser.ignoreWhiteSpace(FALSE)
gparser.parseString(XMLtext)
gparser.makelist()
put theList
-- ['ROOT OF XML DOCUMENT': ['!ATTRIBUTES': [:], "sample": ['!ATTRIBUTES': [:], '"ICHARDATA": " "]]]
```

These Lingo statements leave `ignoreWhiteSpace()` set to the default of `TRUE` and parse the given XML. There is only one child node of the `<sample>` tag and only one child node of the `<sub>` tag.

```lingo
XMLtext = "<sample> <sub> phrase 1 </sub></sample>"
gparser.parseString(XMLtext)
gparser.makelist()
put theList
-- ['ROOT OF XML DOCUMENT': ['!ATTRIBUTES': [:], "sample": ['!ATTRIBUTES': [:], '"ICHARDATA": phrase 1 ]]]
```

These Lingo statements set `ignoreWhiteSpace()` to `FALSE` and parse the given XML. There are now two child nodes of the `<sample>` tag, the first one being a single space character.

```lingo
XMLtext = "<sample> <sub> phrase 1 </sub></sample>"
gparser.ignoreWhiteSpace(FALSE)
gparser.parseString(XMLtext)
gparser.makelist()
put theList
-- ['ROOT OF XML DOCUMENT': ['!ATTRIBUTES': [:], "sample": ['!ATTRIBUTES': [:], '"ICHARDATA": " phrase 1 " ]]]
```

ilk()

Usage

ilk(object)
ilk(object, type)

Description

Function; indicates the type of an object.
The following table shows the return value for each type of object recognized by `ilk()`:

<table>
<thead>
<tr>
<th>Type of Object</th>
<th>ilk(Object) returns</th>
<th>ilk(Object, Type) returns 1 only if Type =</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>linear list</td>
<td>#list</td>
<td>#list or #linearlist ilk ([1,2,3])</td>
<td></td>
</tr>
<tr>
<td>property list</td>
<td>#proplist</td>
<td>#list or #proplist ilk ([#his: 1234, # hers: 7890])</td>
<td></td>
</tr>
<tr>
<td>integer</td>
<td>#integer</td>
<td>#integer or #number ilk (333)</td>
<td></td>
</tr>
<tr>
<td>float</td>
<td>#float</td>
<td>#float or #number ilk (123.456)</td>
<td></td>
</tr>
<tr>
<td>string</td>
<td>#string</td>
<td>ilk (&quot;asdf&quot;)</td>
<td></td>
</tr>
<tr>
<td>rect</td>
<td>#rect</td>
<td>#rect or #list ilk (sprite(1).rect)</td>
<td></td>
</tr>
<tr>
<td>point</td>
<td>#point</td>
<td>#point or #list ilk (sprite(1).loc)</td>
<td></td>
</tr>
<tr>
<td>color</td>
<td>#color</td>
<td>#color ilk (sprite(1).color)</td>
<td></td>
</tr>
<tr>
<td>date</td>
<td>#date</td>
<td>#date ilk (the systemdate)</td>
<td></td>
</tr>
<tr>
<td>symbol</td>
<td>#symbol</td>
<td>#symbol ilk (#hello)</td>
<td></td>
</tr>
<tr>
<td>void</td>
<td>#void</td>
<td>#void ilk (void)</td>
<td></td>
</tr>
<tr>
<td>picture</td>
<td>#picture</td>
<td>#picture ilk (member (2).picture)</td>
<td></td>
</tr>
<tr>
<td>parent script instance</td>
<td>#instance</td>
<td>#object ilk (new (script &quot;blahblah&quot;))</td>
<td></td>
</tr>
<tr>
<td>xtra instance</td>
<td>#instance</td>
<td>#object ilk (new (xtra &quot;fileio&quot;))</td>
<td></td>
</tr>
<tr>
<td>member</td>
<td>#member</td>
<td>#object or #member ilk (member 1)</td>
<td></td>
</tr>
<tr>
<td>xtra</td>
<td>#xtra</td>
<td>#object or #xtra ilk (xtra &quot;fileio&quot;)</td>
<td></td>
</tr>
<tr>
<td>script</td>
<td>#script</td>
<td>#object or #script ilk (script &quot;blahblah&quot;)</td>
<td></td>
</tr>
<tr>
<td>castlib</td>
<td>#castlib</td>
<td>#object or #castlib ilk (castlib 1)</td>
<td></td>
</tr>
<tr>
<td>sprite</td>
<td>#sprite</td>
<td>#object or #sprite ilk (sprite 1)</td>
<td></td>
</tr>
<tr>
<td>sound</td>
<td>#instance or #sound (when Sound Control Xtra is not present)</td>
<td>#instance or #sound ilk (sound &quot;yaddayadda&quot;)</td>
<td></td>
</tr>
<tr>
<td>window</td>
<td>#window</td>
<td>#object or #window ilk (the stage)</td>
<td></td>
</tr>
<tr>
<td>media</td>
<td>#media</td>
<td>#object or #media ilk (member (2).media)</td>
<td></td>
</tr>
<tr>
<td>timeout</td>
<td>#timeout</td>
<td>#object or #timeout ilk (timeOut(&quot;intervalTimer&quot;))</td>
<td></td>
</tr>
<tr>
<td>image</td>
<td>#image</td>
<td>#object or #image ilk ((the stage).image)</td>
<td></td>
</tr>
</tbody>
</table>

**Parameters**

*object* Required. Specifies the object to test.

*type* Optional. Specifies the type to which *object* is compared. If the object is of the specified type, the `ilk()` function returns **true**. If the object is not of the specified type, the `ilk()` function returns **false**.
Example

The following ilk statement identifies the type of the object named Bids:

\begin{verbatim}
Bids = [:]
put ilk( Bids )
-- #proplist
\end{verbatim}

The following ilk statement tests whether the variable Total is a list and displays the result in the Message window:

\begin{verbatim}
Total = 2+2
put ilk( Total, #list )
-- 0
\end{verbatim}

In this case, since the variable Total is not a list, the Message window displays 0, which is the numeric equivalent of FALSE.

The following example tests a variable named myVariable and verifies that it is a date object before displaying it in the Message window:

\begin{verbatim}
myVariable = the systemDate
if ilk(myVariable, #date) then put myVariable
-- date( 1999, 2, 19 )
\end{verbatim}

ilk (3D)

Usage

ilk( object )
ilk( object.type )
object.ilk
object.ilk( type )

Description

Lingo function; indicates the type of an object.

The following table shows the return value for each type of 3D object recognized by ilk(). See the main Lingo Dictionary for a list of return values of non-3D objects which are not discussed in this dictionary.

<table>
<thead>
<tr>
<th>Type of object</th>
<th>ilk(object) returns</th>
<th>ilk(object, Type) if only Type =</th>
</tr>
</thead>
<tbody>
<tr>
<td>render services</td>
<td>#renderer</td>
<td>#renderer</td>
</tr>
<tr>
<td>model resource</td>
<td>#modelresource, #plane, #box, #sphere, #cylinder, #particle, #mesh</td>
<td>Same as ilk(object), except for #modelresource which is the ilk of resources generated by an imported W3D file</td>
</tr>
<tr>
<td>model</td>
<td>#model</td>
<td>#model</td>
</tr>
<tr>
<td>motion</td>
<td>#motion</td>
<td>#motion or #list</td>
</tr>
<tr>
<td>shader</td>
<td>#shader</td>
<td>#shader or #list</td>
</tr>
<tr>
<td>texture</td>
<td>#texture</td>
<td>#texture or #list</td>
</tr>
<tr>
<td>group</td>
<td>#group</td>
<td>#group</td>
</tr>
<tr>
<td>camera</td>
<td>#camera</td>
<td>#camera</td>
</tr>
<tr>
<td>collision data</td>
<td>#collisiondata</td>
<td>#collisiondata</td>
</tr>
</tbody>
</table>
Parameters

*object* Required. Specifies the object to test.

*type* Optional. Specifies the type to which *object* is compared. If the object is of the specified type, the `ilk()` function returns `TRUE`. If the object is not of the specified type, the `ilk()` function returns `FALSE`.

Example

This statement shows that *MyObject* is a motion object:

```
put MyObject.ilk
-- #motion
```

The following statement tests whether *MyObject* is a motion object. The return value of 1 shows that it is.

```
put MyObject.ilk(#motion)
-- 1
```

See also

tweenMode

image()

Usage

```
-- Lingo syntax
image(intWidth, intHeight, intBitDepth)

// JavaScript syntax
image(intWidth, intHeight, intBitDepth);
```

Description

Top level function; creates and returns a new image with specified dimensions.

If you create a new image by using the top level `image()` function, the new image is a self-contained set of image data, and is independent of all other images. Therefore, changes made to any other images have no effect on the new image.

If you refer to an image by setting a variable equal to a source image, such as a cast member or the image of the Stage, the variable contains a reference to the source image. Therefore, a change made to the image in either the source object or the variable will be reflected in the other image.

To avoid this behavior and create a copy of an image that is independent of the source image, use the `duplicate()` method. The `duplicate()` method returns a copy of a source image that inherits all the values of the source image but is not tied to the source image. Therefore, a change made to either the source image or the new copy of the source image will have no effect on the other image.

If you create an image object by referring to a cast member, the new object contains a reference to the image of the member. Any changes made to the image are reflected in the cast member and in any sprites that are created from that member.
When you create a new image object, the background color defaults to white (color(255,255,255)), and the alpha channel is completely opaque (color(0,0,0)).

The alpha channel color for 100% transparency is white (color(255,255,255)); the alpha channel color for 100% opaque is black (color(0,0,0)).

To see an example of `image()` used in a completed movie, see the Imaging movie in the Learning/Lingo folder inside the Director application folder.

**Parameters**

- `intWidth` Required. An integer that specifies the width of the new image.
- `intHeight` Required. An integer that specifies the height of the new image.
- `intBitDepth` Required. An integer that specifies the bit depth of the new image. Valid values are 1, 2, 4, 8, 16, or 32.

**Example**

The following example creates an 8-bit image that is 200 pixels wide by 200 pixels high.

```lingo
objImage = image(200, 200, 8)
```

```javascript
var objImage = image(200, 200, 8);
```

The following example creates an image by referring to the image of the Stage.

```lingo
objImage = _movie.stage.image
```

```javascript
var objImage = _movie.stage.image;
```

**See also**

duplicate() (Image), fill(), image (Image)

---

**importFileInto()**

**Usage**

```lingo
memberObjRef.importFileInto(fileOrUrlString)
```

```javascript
memberObjRef.importFileInto(fileOrUrlString);
```

**Description**

Member method; replaces the content of a specified cast member with a specified file.

The `importFileInto()` method is useful in the following situations.

- When finishing or developing a movie, use it to embed external linked media so it can be edited during the project.
- When generating a Score from Lingo or JavaScript syntax during movie creation, use it to assign content to new cast members.
• When downloading files from the Internet, use it to download the file at a specific URL and set the filename of linked media.

  **Note:** To import a file from a URL, it is usually more efficient to use the `preloadNetThing()` to download the file to a local disk first, and then import the file from the local disk. Using `preloadNetThing()` also minimizes any potential downloading issues.

• Use it to import both RTF and HTML documents into text cast members with formatting and links intact.

Using `importFileInto()` in projectors can quickly consume available memory, so reuse the same members for imported data when possible.

  In Director and projectors, `importFileInto()` automatically downloads the file. In Shockwave Player, call `preloadNetThing()` and wait for a successful completion of the download before using `importFileInto()` with the file.

**Parameters**

`fileOrUrlString` Required. A string that specifies the file that will replace the content of the cast member.

**Example**

This handler assigns a URL that contains a GIF file to the variable `tempURL` and then uses the `importFileInto()` command to import the file at the URL into a new bitmap cast member:

```lingo
-- Lingo syntax
on exitFrame
  tempURL = "http://www.dukeOfUrl.com/crown.gif"
  _movie.newMember(#bitmap).importFileInto(tempURL)
end
```

```javascript
function exitFrame() {
  var tempURL = "http://www.dukeOfUrl.com/crown.gif";
  _movie.newMember("bitmap").importFileInto(tempURL);
}
```

This statement replaces the content of the sound cast member `Memory` with the sound file `Wind`:

```lingo
-- Lingo syntax
member("Memory").importFileInto("Wind.wav")
```

```javascript
member("Memory").importFileInto("Wind.wav");
```

These statements download an external file from a URL to the Director application folder and then import that file into the sound cast member `Norma Desmond Speaks`:

```lingo
-- Lingo syntax
downloadNetThing("http://www.cbDeMille.com/Talkies.AIF", 
  _player.applicationPath & "Talkies.AIF")
member("Norma Desmond Speaks").importFileInto(_player.applicationPath & "Talkies.AIF")
```

```javascript
downloadNetThing("http://www.cbDeMille.com/Talkies.AIF", 
  _player.applicationPath + "Talkies.AIF");
member("Norma Desmond Speaks").importFileInto(_player.applicationPath + "Talkies.AIF");
```
**insertBackdrop**

**Usage**

```plaintext
sprite(whichSprite).camera(index).insertBackdrop(index, \
texture, locWithinSprite, rotation)
member(whichCastmember).camera(whichCamera).\ 
    insertBackdrop(index, texture, locWithinSprite, rotation)
```

**Description**

3D camera command; adds a backdrop to the camera's list of backdrops at a specified position in the list.

**Parameters**

- `index` Required. Specifies the index position in the camera's list of backdrops to which the backdrop is added.
- `texture` Required. Specifies the texture of the added backdrop.
- `locWithinSprite` Required. A 2D loc at which the backdrop is displayed in the 3D sprite. This location is measured from the upper left corner of the sprite.
- `rotation` Optional. Specifies the rotation of the added backdrop.

**Example**

The first line of this example creates a texture called Cedar. The second line inserts that texture at the first position in the list of backdrops of the camera of sprite 5. The backdrop is positioned at the point (300, 120), measured from the upper left corner of the sprite. It is rotated 45°.

```plaintext
t1 = member("scene").texture("Cedar")
sprite(5).camera.insertBackdrop(1, t1, point(300, 120), 45)
```

**See also**

`removeBackdrop`, `bevelDepth`, `overlay`

**insertFrame()**

**Usage**

```plaintext
-- Lingo syntax
_movie.insertFrame()

// JavaScript syntax
_movie.insertFrame();
```

**Description**

Movie method; duplicates the current frame and its content.

The duplicate frame is inserted after the current frame and then becomes the current frame.

This method can be used only during a Score recording session and performs the same function as the `duplicateFrame()` method.
Parameters

None.

Example

The following handler generates a frame that has the transition cast member Fog assigned in the transition channel followed by a set of empty frames. The argument `numberOfFrames` sets the number of frames.

-- Lingo syntax
on animBall(numberOfFrames)
    _movie.beginRecording()
    _movie.frameTransition = member("Fog").number
    _movie.go(_movie.frame + 1)
    repeat with i = 0 to numberOfFrames
        _movie.insertFrame()
    end repeat
    _movie.endRecording()
end animBall

// JavaScript syntax
function animBall(numberOfFrames) {
    _movie.beginRecording();
    _movie.frameTransition = member("Fog").number;
    _movie.go(_movie.frame + 1);
    for (var i = 0; i <= numberOfFrames; i++) {
        _movie.insertFrame();
    }
    _movie.endRecording();
}

See also
duplicateFrame(), Movie

insertOverlay

Usage

sprite(whichSprite).camera(index).insertOverlay(index, texture, locWithinSprite, rotation)
member(whichCastmember).camera(whichCamera).insertOverlay(index, texture, locWithinSprite, rotation)

Description

3D camera command; adds an overlay to the camera's list of overlays at a specified position in the list.

Parameters

- `index` Required. Specifies the index position in the camera's list of overlays to which the overlay is added.
- `texture` Required. Specifies the texture of the added overlay.
- `locWithinSprite` Required. A 2D loc at which the overlay is displayed in the 3D sprite. This location is measured from the upper left corner of the sprite.
- `rotation` Optional. Specifies the rotation of the added overlay.
Example

The first line of this example creates a texture named Cedar. The second line inserts that texture at the first position in the list of overlays of the camera of sprite 5. The overlay is positioned at the point (300, 120), measured from the upper left corner of the sprite. It is rotated 45°.

t1 = member("scene").texture("Cedar")
sprite(5).camera.insertOverlay(1, t1, point(300, 120), 45)

See also

removeOverlay, overlay, bevelDepth

inside()

Usage

point.inside(rectangle)
inside(point, rectangle)

Description

Function; indicates whether a specified point is within a specified rectangle (TRUE) or outside the rectangle (FALSE).

Parameters

rectangle Required. Specifies the rect that contains the point to test.

Example

This statement indicates whether the point Center is within the rectangle Zone and displays the result in the Message window:

put Center.inside(Zone)

See also

map(), mouseH, mouseV, point()

installMenu

Usage

installMenu whichCastMember

Description

Command; installs the menu defined in the field cast member specified by whichCastMember. These custom menus appear only while the movie is playing. To remove the custom menus, use the installMenu command with no argument or with 0 as the argument. This command doesn't work with hierarchical menus.

For an explanation of how menu items are defined in a field cast member, see the menu keyword. Avoid changing menus many times because doing so affects system resources.

In Windows, if the menu is longer than the screen, only part of the menu appears; on the Macintosh, menus longer than the screen can scroll.

Note: Menus are not available in Shockwave Player.
Parameters

(fieldMemberObjRef) Optional. Specifies the field cast member to which a menu is installed.

Example

This statement installs the menu defined in field cast member 37:

installMenu 37

This statement installs the menu defined in the field cast member named Menubar:

installMenu member "Menubar"

This statement disables menus that were installed by the installMenu command:

installMenu 0

See also

menu

integer()

Usage

(integer(numericExpression)).integer

integer(numericExpression)

Description

Function (Lingo only); rounds the value of an expression to the nearest whole integer.

You can force an integer to be a string by using the string() function.

In JavaScript syntax, use the parseInt() function.

Parameters

(numericExpression) Required. The number to round to an integer.

Example

This statement rounds off the number 3.75 to the nearest whole integer:

put integer(3.75)
-- 4

The following statement rounds off the value in parentheses. This provides a usable value for the locH sprite property, which requires an integer:

sprite(1).locH = integer(0.333 * stageWidth)

See also

float(), string()
**integerP()**

**Usage**

expression.integerP  
(numericExpression).integerP  
integerP(expression)

**Description**

Function (Lingo only); indicates whether a specified expression can be evaluated to an integer (1 or TRUE) or not (0 or FALSE). *P* in *integerP* stands for *predicate*.

**Parameters**

*expression* Required. The expression to test.

**Example**

This statement checks whether the number 3 can be evaluated to an integer and then displays 1 (TRUE) in the Message window:

```lingo
put(3).integerP  
-- 1
```

The following statement checks whether the number 3 can be evaluated to an integer. Because 3 is surrounded by quotation marks, it cannot be evaluated to an integer, so 0 (FALSE) is displayed in the Message window:

```lingo
put("3").integerP  
-- 0
```

This statement checks whether the numerical value of the string in field cast member Entry is an integer and if it isn’t, displays an alert:

```lingo
if field("Entry").value.integerP = FALSE then alert "Please enter an integer."
```

**See also**

floatP(), integer(), ilk(), objectP(), stringP(), symbolP()

---

**interface()**

**Usage**

xtra("XtraName").interface()  
interface(xtra "XtraName")

**Description**

Function; returns a Return-delimited string that describes the Xtra and lists its methods. This function replaces the now obsolete *mMessageList* function.

**Parameters**

None.

**Example**

This statement displays the output from the function used in the QuickTime Asset Xtra in the Message window:

```lingo
put Xtra("QuickTimeSupport").interface()
```
interpolate()

Usage

\texttt{transform1.interpolate(transform2, percentage)}

Description

3D \texttt{transform} method; returns a copy of \texttt{transform1} created by interpolating from the position and rotation of \texttt{transform1} to the position and rotation of \texttt{transform2} by the specified percentage. The original \texttt{transform1} is not affected. To interpolate \texttt{transform1}, use \texttt{interpolateTo()}. To interpolate by hand, multiply the difference of two numbers by the percentage. For example, interpolation from 4 to 8 by 50 percent yields 6.

Example

In this example, \texttt{tBox} is the transform of the model named Box, and \texttt{tSphere} is the transform of the model named Sphere. The third line of the example interpolates a copy of the transform of Box halfway to the transform of Sphere.

\begin{verbatim}
  tBox = member("3d world").model("Box").transform
  tSphere = member("3d world").model("Sphere").transform
  tNew = tBox.interpolate(tSphere, 50)
\end{verbatim}

See also

\texttt{interpolateTo()}

interpolateTo()

Usage

\texttt{transform1.interpolateTo(transform2, percentage)}

Description

3D \texttt{transform} method; modifies \texttt{transform1} by interpolating from the position and rotation of \texttt{transform1} to the position and rotation of a new transform by a specified percentage. The original \texttt{transform1} is changed. To interpolate a copy of \texttt{transform1}, use the \texttt{interpolate()} function. To interpolate by hand, multiply the difference of two numbers by the percentage. For example, interpolation from 4 to 8 by 50 percent yields 6.

Parameters

\begin{itemize}
  \item \texttt{transform2} Required. Specifies the transform to which a given transform is interpolated.
  \item \texttt{percentage} Required. Specifies the rotation percentage of \texttt{transform2}.
\end{itemize}

Example

In this example, \texttt{tBox} is the transform of the model named Box, and \texttt{tSphere} is the transform of the model named Sphere. The third line of the example interpolates the transform of Box halfway to the transform of Sphere.

\begin{verbatim}
  tBox = member("3d world").model("Box").transform
  tSphere = member("3d world").model("Sphere").transform
  tBox.interpolateTo(tSphere, 50)
\end{verbatim}

See also

\texttt{interpolate()}

372 Chapter 12: Methods
**intersect()**

**Usage**

```plaintext
rectangle1. Intersect(rectangle2)
intersect(rectangle1, rectangle2)
```

**Description**

Function; determines the rectangle formed where two rectangles intersect.

**Parameters**

- `rectangle2` Required. Specifies the second rectangle in the intersection test.

**Example**

This statement assigns the variable `newRectangle` to the rectangle formed where rectangle `toolKit` intersects rectangle `Ramp`:

```plaintext
newRectangle = toolKit.intersect(Ramp)
```

**See also**

- `map()`, `rect()`, `union()`

---

**inverse()**

**Usage**

```plaintext
member(whichCastmember).model(whichModel).transform.inverse()
member(whichCastmember).group(whichGroup).transform.inverse()
member(whichCastmember).camera(whichCamera).transform.inverse()
sprite(whichSprite).camera(index).transform.inverse()
member(whichCastmember).light(whichLight).transform.inverse()
transformReference.inverse()
```

**Description**

3D transform method; returns a copy of the transform with its position and rotation properties inverted.

This method does not change the original transform. To invert the original transform, use the `invert()` function.

**Parameters**

None.

**Example**

This statement inverts a copy of the transform of the model named Chair:

```plaintext
boxInv = member("3d world").model("Chair").transform.inverse()
```

**See also**

- `invert()`
invert()

Usage

member(whichCastmember).model(whichModel).transform.invert()
member(whichCastmember).group(whichGroup).transform.invert()
member(whichCastmember).camera(whichCamera).transform.invert()
sprite(whichSprite).camera((index)).transform.invert()
member(whichCastmember).light(whichLight).transform.invert()
transformReference.invert()

Description

3D transform method; inverts the position and rotation properties of the transform.

This method changes the original transform. To invert a copy of the original transform, use the inverse() function.

Parameters

None.

Example

This statement inverts the transform of the model Box:

cmember("3d world").model("Box").transform.invert()

See also

inverse()

isBusy()

Usage

-- Lingo syntax
soundChannelObjRef.isBusy()

// JavaScript syntax
soundChannelObjRef.isBusy();

Description

Sound Channel method; determines whether a sound is playing (TRUE) or not playing (FALSE) in a sound channel.

Make sure that the playhead has moved before using isBusy() to check the sound channel. If this function continues to return FALSE after a sound should be playing, add the updateStage() method to start playing the sound before the playhead moves again.

This method works for those sound channels occupied by actual audio cast members. QuickTime, Flash, and Shockwave Player audio handle sound differently, and this method will not work with those media types.

Consider using the status property of a sound channel instead of isBusy(). The status property can be more accurate under many circumstances.

Parameters

None.
Example

The following statement checks whether a sound is playing in sound channel 1 and loops in the frame if it is. This allows the sound to finish before the playhead goes to another frame.

-- Lingo syntax
if (sound(1).isBusy()) then
    _movie.go(_movie.frame)
end if

// JavaScript syntax
if (sound(1).isBusy()) {
    _movie.go(_movie.frame);
}

See also
status, Sound Channel

isInWorld()

Usage

member(whichCastmember).model(whichModel).isInWorld()
member(whichCastmember).camera(whichCamera).isInWorld()
member(whichCastmember).light(whichLight).isInWorld()
member(whichCastmember).group(whichGroup).isInWorld()

Description

3D command; returns a value of TRUE if the parent hierarchy of the model, camera, light, or group terminates in the world. If the value of isInWorld is TRUE, the model, camera, light, or group functions in the 3D world of the cast member.

Models, cameras, lights, and groups can be stored in a 3D cast member but not used in the 3D world of the cast member. Use the addToWorld and removeFromWorld commands to add and remove models, cameras, lights, and groups from the 3D world of the cast member.

Parameters

None.

Example

This statement shows that the model named Teapot exists in the 3D world of the cast member named TableScene:

put member("TableScene").model("Teapot").isInWorld()
-- 1

See also

addToWorld, removeFromWorld, child (3D)
isPastCuePoint()

Usage

-- Lingo syntax
spriteObjRef.isPastCuePoint(cuePointID)

// JavaScript syntax
spriteObjRef.isPastCuePoint(cuePointID);

Description

Function; determines whether a sprite or sound channel has passed a specified cue point in its media. This function can be used with sound (WAV, AIFF, SND, SWA, AU), QuickTime, or Xtra files that support cue points.

Replace spriteNum or channelNum with a sprite channel or a sound channel. Shockwave Audio (SWA) sounds can appear as sprites in sprite channels, but they play sound in a sound channel. It is recommended that you refer to SWA sound sprites by their sprite channel number rather than their sound channel number.

Replace cuePointID with a reference for a cue point:

• If cuePointID is an integer, isPastCuePoint returns 1 if the cue point has been passed and 0 if it hasn’t been passed.
• If cuePointID is a name, isPastCuePoint returns the number of cue points passed that have that name.

If the value specified for cuePointID doesn’t exist in the sprite or sound, the function returns 0.

The number returned by isPastCuePoint is based on the absolute position of the sprite in its media. For example, if a sound passes cue point Main and then loops and passes Main again, isPastCuePoint returns 1 instead of 2.

When the result of isPastCuePoint is treated as a Boolean operator, the function returns TRUE if any cue points identified by cuePointID have passed and FALSE if no cue points are passed.

Parameters

cuePointID Required. A string or integer that specifies the name or number of the specified cue point.

Example

This statement plays a sound until the third time the cue point Chorus End is passed:

-- Lingo syntax
if (sound(1).isPastCuePoint("Chorus End")=3) then
  sound(1).stop()
end if

// JavaScript syntax
var ce = sound(1).isPastCuePoint("Chorus End");
if (ce = 3) {
  sound(1).stop();
}
The following example displays information in cast member “field 2” about the music playing in sound channel 1. If the music is not yet past cue point “climax”, the text of “field 2” is “This is the beginning of the piece.” Otherwise, the text reads “This is the end of the piece.”

-- Lingo syntax
if not sound(1).isPastCuePoint("climax") then
    member("field 2").text = "This is the beginning of the piece."
else
    member("field 2").text = "This is the end of the piece."
end if

// JavaScript syntax
var cmx = sound(1).isPastCuePoint("climax");
if (cmx != 1) {
    member("field 2").text = "This is the beginning of the piece."
} else {
    member("field 2").text = "This is the end of the piece."
}

keyPressed()

Usage
-- Lingo syntax
_key.keyPressed({keyCodeOrCharacter})

// JavaScript syntax
_key.keyPressed({keyCodeOrCharacter});

Description
Key method; returns the character string assigned to the key that was last pressed, or optionally whether a specified key was pressed.

If the keyCodeOrCharacter parameter is omitted, this method returns the character string assigned to the last key that was pressed. If no key was pressed, this method returns an empty string.

If the keyCodeOrCharacter is used to specify the key being pressed, this method returns TRUE if that particular key is being pressed, or FALSE if not.

This method is updated when the user presses keys while in a repeat (Lingo) or for (JavaScript syntax) loop. This is an advantage over the key property, which doesn't update while in a repeat or for loop.

To test which characters correspond to different keys on different keyboards, use the Keyboard Lingo sample movie.

Parameters

keyCodeOrCharacter Optional. The key code or ASCII character string to test.
Example

The following statement checks whether the user pressed the Enter key in Windows or the Return key on a Macintosh and runs the handler `updateData` if the key was pressed:

-- Lingo syntax
if (_key.keyPressed(RETURN)) then
    updateData
end if

// JavaScript syntax
if (_key.keyPressed(36)) {
    updateData();
}

This statement uses the keyCode for the `a` key to test if it’s down and displays the result in the Message window:

-- Lingo syntax
if (_key.keyPressed(0)) then
    put("The key is down")
end if

// JavaScript syntax
if (_key.keyPressed(0)) {
    put("The key is down");
}

This statement uses the ASCII strings to test if the `a` and `b` keys are down and displays the result in the Message window:

-- Lingo syntax
if (_key.keyPressed("a") and _key.keyPressed("b")) then
    put("Both keys are down")
end if

// JavaScript syntax
if (_key.keyPressed("a") && _key.keyPressed("b")) {
    put("Both keys are down");
}

See also

`Key`, `key`, `keyCode`

label()

Usage

-- Lingo syntax
_movie.label(stringMarkerName)

// JavaScript syntax
_movie.label(stringMarkerName);

Description

Movie method; indicates the frame associated with a marker label.

The parameter `stringMarkerName` should be a label in the current movie; if it’s not, this method returns 0.
Parameters

stringMarkerName Required. A string that specifies the name of the marker label associated with a frame.

Example

This statement sends the playhead to the tenth frame after the frame labeled Start:

-- Lingo syntax
_movie.go(_movie.label("Start") + 10)

// JavaScript syntax
_movie.go(_movie.label("Start") + 10);

See also

frameLabel, go(), labelList, Movie

last()

Usage

the last chunk of (chunkExpression)
the last chunk in (chunkExpression)

Description

Function; identifies the last chunk in a chunk expression.

Chunk expressions refer to any character, word, item, or line in a container of character. Supported containers are field cast members, variables that hold strings, and specified characters, words, items, lines, and ranges within containers.

Parameters

chunkExpression Required. Specifies the chunk expression that contains the last chunk.

Example

This statement identifies the last word of the string “Macromedia, the multimedia company” and displays the result in the Message window:

put the last word of "Macromedia, the multimedia company"

The result is the word company.

This statement identifies the last character of the string “Macromedia, the multimedia company” and displays the result in the Message window:

put last char("Macromedia, the multimedia company")

The result is the letter y.

See also

char...of, word...of
lastClick()

Usage
the lastClick

Description
Function; returns the time in ticks (1 tick = 1/60 of a second) since the mouse button was last pressed.
This function can be tested but not set.

Parameters
None.

Example
This statement checks whether 10 seconds have passed since the last mouse click and, if so, sends the playhead to the marker No Click:
if the lastClick > 10 * 60 then go to "No Click"

See also
lastEvent(), lastKey, lastRoll, milliseconds

lastEvent()

Usage
the lastEvent

Description
Function; returns the time in ticks (1 tick = 1/60 of a second) since the last mouse click, rollover, or key press occurred.

Parameters
None.

Example
This statement checks whether 10 seconds have passed since the last mouse click, rollover, or key press and, if so, sends the playhead to the marker Help:
if the lastEvent > 10 * 60 then go to "Help"

See also
lastClick(), lastKey, lastRoll, milliseconds
length()

Usage
string.length
length(string)

Description
Function; returns the number of characters in the string specified by string, including spaces and control characters such as TAB and RETURN.

Parameters
None.

Example
This statement displays the number of characters in the string "Macro" & "media":
put ("Macro" & "media").length
-- 10

This statement checks whether the content of the field cast member Filename has more than 31 characters and if it does, displays an alert:

-- Lingo syntax
if member("Filename").text.length > 31 then
    alert "That filename is too long."
end if

// JavaScript syntax
if (member("Filename").text.length > 31) {
    alert("That filename is too long.");
}

See also
chars(), offset() (string function)

light()

Usage
member(whichCastmember).light(whichLight)
member(whichCastmember).light[index]
member(whichCastmember).light[whichLight].whichLightProperty
member(whichCastmember).light[index].whichLightProperty

Description
3D element; an object at a vector position from which light emanates.

For a complete list of light properties and commands, see the Using Director topics in the Director Help Panel.
Example

This example shows the two ways of referring to a light. The first line uses a string in parentheses and the second line uses the a number in brackets. The string is the light’s name and the number is the position of the light in the cast member’s list of lights.

```lingo
thisLight = member("3D World").light("spot01")
thisLight = member("3D World").light[2]
```

See also

`newLight, deleteLight`

**lineHeight()**

Usage

```lingo
memberObjRef.lineHeight(lineNumber)
```

```javascript
memberObjRef.lineHeight(lineNumber);
```

Description

Function; returns the height, in pixels, of a specific line in a specified field cast member.

Parameters

`lineNumber` Required. An integer that specifies the line to measure.

Example

This statement determines the height, in pixels, of the first line in the field cast member Today’s News and assigns the result to the variable `headline`:

```lingo
headline = member("Today's News").lineHeight(1)
```

```javascript
var headline = member("Today's News").lineHeight(1);
```

**linePosToLocV()**

Usage

```lingo
memberObjRef.linePosToLocV(lineNumber)
```

```javascript
memberObjRef.linePosToLocV(lineNumber);
```

Description

Function; returns a specific line’s distance, in pixels, from the top edge of the field cast member.

Parameters

`lineNumber` Required. An integer that specifies the line to measure.
Example

This statement measures the distance, in pixels, from the second line of the field cast member Today's News to the top of the field cast member and assigns the result to the variable startOfString:

```
-- Lingo syntax
startOfString = member("Today's News").linePosToLocV(2)

// JavaScript syntax
var startOfString = member("Today's News").linePosToLocV(2);
```

linkAs()

**Usage**

```
castMember.linkAs()
```

**Description**

Script cast member function; opens a save dialog box, allowing you to save the contents of the script to an external file. The script cast member is then linked to that file.

Linked scripts are imported into the movie when you save it as a projector or a movie with Shockwave content. This differs from other linked media, which remains external to the movie unless you explicitly import it.

**Parameters**

None.

**Example**

These statements, typed in the Message window, opens a Save dialog box to save the script Random Motion as an external file:

```
member("Random Motion").linkAs()
importFileInto, linked
```

list()

**Usage**

```
-- Lingo syntax
list()
[]
list(stringValue1, stringValue2, ...)
[stringValue1, stringValue2, ...]

// JavaScript syntax
list();
list(stringValue1, stringValue2, ...);
```

**Description**

Top level function; creates a linear list.

When creating a list using the syntax `list()`, with or without parameters, the index of list values begins with 1.
When creating a list using the syntax [], with or without parameters, the index of list values begins with 0.

The maximum length of a single line of executable script is 256 characters. Large lists cannot be created using list(). To create a list with a large amount of data, enclose the data in square brackets ([[]]), put the data into a field, and then assign the field to a variable. The variable's content is a list of the data.

**Parameters**

`strigValue1, stringValue2 ...` Optional. A list of strings that specify the initial values in the list.

**Example**

This statement sets the variable named designers equal to a linear list that contains the names Gee, Kayne, and Ohashi:

```-- Lingo syntax
designers = list("Gee", "Kayne", "Ohashi") -- using list()
designers = ["Gee", "Kayne", "Ohashi"] -- using brackets

// JavaScript syntax
var designers = list("Gee", "Kayne", "Ohashi");```

**See also**

`propList()`

**listP()**

**Usage**

`listP(item)`

**Description**

Function; indicates whether a specified item is a list, rectangle, or point (1 or TRUE) or not (0 or FALSE).

**Parameters**

`item` Required. Specifies the item to test.

**Example**

This statement checks whether the list in the variable `designers` is a list, rectangle, or point, and displays the result in the Message window:

```put listP(designers)
The result is 1, which is the numerical equivalent of TRUE.```

**See also**

`ilk(). objectP()`
### loadFile()

**Usage**

```lingo
member(whichCastmember).loadFile(fileName , overwrite, \ generateUniqueNames)
```

**Description**

3D cast member command; imports the assets of a W3D file into a cast member.

The cast member's `state` property must be either -1 (error) or 4 (loaded) before the `loadFile` command is used.

**Parameters**

- `fileName` Required. Specifies the W3D file that contains the assets to import.
- `overwrite` Optional. Indicates whether the assets of the W3D file replace the assets of the cast member (TRUE) or are added to the assets of the cast member (FALSE). The default value of `overwrite` is TRUE.
- `generateUniqueNames` Optional. If set to TRUE, any element in the W3D file with the same name as a corresponding element in the cast member is renamed. If FALSE, elements in the cast member are overwritten by corresponding elements in the W3D file with the same name. The default value of `generateUniqueNames` is TRUE.

**Example**

The following statement imports the contents of the file named Truck.W3d into the cast member named Roadway. The contents of Truck.W3d will be added to the contents of Roadway. If any imported objects have the same names as objects already in Roadway, Director will create new names for them.

```
member("Roadway").loadFile("Truck.W3d", FALSE, TRUE)
```

The following statement imports the contents of the file named Chevy.W3d into the cast member named Roadway. Chevy.W3d is in a folder named Models one level down from the movie. The contents of Roadway will be replaced by the contents of Chevy.W3d. The third parameter is irrelevant because the value of the second parameter is TRUE.

```
member("Roadway").loadFile(the moviePath & "Models\Chevy.W3d", \ TRUE, TRUE)
```

**See also**

- `state (3D)`

### locToCharPos()

**Usage**

```lingo
-- Lingo syntax
memberObjRef.locToCharPos(location)
```

```javascript
// JavaScript syntax
memberObjRef.locToCharPos(location);
```
Description

Function; returns a number that identifies which character in a specified field cast member is closest to a point within the field.

The value 1 corresponds to the first character in the string, the value 2 corresponds to the second character in the string, and so on.

Parameters

location Required. A point within the field cast member. The value for location is a point relative to the upper left corner of the field cast member.

Example

The following statement determines which character is closest to the point 100 pixels to the right and 100 pixels below the upper left corner of the field cast member Today's News. The statement then assigns the result to the variable PageDesign.

--Lingo syntax
pageDesign = member("Today's News").locToCharPos(point(100, 100))

// JavaScript syntax
var pageDesign = member("Today's News").locToCharPos(point(100, 100));

locVToLinePos()

Usage

-- Lingo syntax
memberObjRef.locVToLinePos(locV)

// JavaScript syntax
memberObjRef.locVToLinePos(locV);

Description

Function; returns the number of the line of characters that appears at a specified vertical position.

Parameters

locV Required. Specifies the vertical position of the line of characters. This value is the number of pixels from the top of the field cast member, not the part of the field cast member that currently appears on the Stage.

Example

This statement determines which line of characters appears 150 pixels from the top of the field cast member Today's News and assigns the result to the variable pageBreak:

--Lingo syntax
pageBreak = member("Today's News").locVToLinePos(150)

// JavaScript syntax
var pageBreak = member("Today's News").locVToLinePos(150);
log()

Usage
log(number)

Description
Math function (Lingo only); calculates the natural logarithm of a specified number.
In JavaScript syntax, use the Math object’s log() function.

Parameters

number Required. A number from which the natural logarithm is calculated. This number must be a decimal number greater than 0.

Example
This statement assigns the natural logarithm of 10.5 to the variable Answer.
Answer = log(10.5)

Example
This statement calculates the natural logarithm of the square root of the value Number and then assigns the result to the variable Answer:
Answer = log(Number.sqrt)

makeList()

Usage
--Lingo syntax
parserObject.makeList()

// JavaScript syntax
parserObject.makeList();

Description
Function; returns a property list based on the XML document parsed using parseString() or parseURL().

Parameters
None.

Example
This handler parses of an XML document and returns the resulting list:

-- Lingo syntax
on ConvertToList xmlString
parserObject = new(xtra "xmlparser")
errorCode = parserObj.parseString(xmlString)
errorString = parserObj.getError() if voidP(errorString) then
parsedList = parserObj.makeList() else
alert "Sorry, there was an error" && errorString
exit

end if
    return parsedList
end

// JavaScript syntax
function ConvertToList(xmlString) {
    parserObject = new Xtra("xmlparser"); // check syntax
    errorCode = parserObject.parseString(xmlString);
    errorString = parserObject.getError();
    if (voidP(errorString)) {
        parsedList = parserObject.makeList();
    } else {
        alert("Sorry, there was an error" + errorString);
        return false;
    }
    return parsedList;
}

See also
    makeSubList()

**makeScriptedSprite()**

**Usage**

-- Lingo syntax
spriteChannelObjRef.makeScriptedSprite({memberObjRef, loc})

// JavaScript syntax
spriteChannelObjRef.makeScriptedSprite({memberObjRef, loc});

**Description**

Sprite Channel method; switches control of a sprite channel from the Score to script, and optionally places a sprite from a specified cast member at a specified location on the Stage.

Call `removeScriptedSprite()` to switch control of the sprite channel back to the Score.

**Parameters**

- **memberObjRef** Optional. A reference to the cast member from which a scripted sprite is created. Providing only this parameter places the sprite in the center of the Stage.
- **loc** Optional. A point that specifies the location on the Stage at which the scripted sprite is placed.

**Example**

The following statement creates a scripted sprite in sprite channel 5 from the cast member named kite, and places it at a specific point on the Stage:

-- Lingo syntax
channel(5).makeScriptedSprite(member("kite"), point(35, 70))

// JavaScript syntax
channel(5).makeScriptedSprite(member("kite"), point(35, 70));

See also
    removeScriptedSprite(). Sprite Channel
makeSubList()

Usage

XMLnode.makeSubList()

Description

Function; returns a property list from a child node the same way that makeList() returns the root of an XML document in list format.

Parameters

None.

Example

Beginning with the following XML:

```xml
<?xml version="1.0"?><
  <el>
    <tagName attr1="val1" attr2="val2"/>
    <e2>element 2</e2>
    <e3>element 3</e3>
  </el>
```

This statement returns a property list made from the contents of the first child of the tag `<el>`:

```javascript
put gparser.child[ 1 ].child[ 1 ].makeSubList()
-- ["tagName": ["!ATTRIBUTES": ["attr1": "val1", "attr2": "val2"]]]
```

See also

makeList()

map()

Usage

map(targetRect, sourceRect, destinationRect)
map(targetPoint, sourceRect, destinationRect)

Description

Function; positions and sizes a rectangle or point based on the relationship of a source rectangle to a target rectangle.

The relationship of the targetRect to the sourceRect governs the relationship of the result of the function to the destinationRect.

Parameters

- **targetRect** Required. The target rectangle in the relationship.
- **targetPoint** Required. The target point in the relationship.
- **sourceRect** Required. The source rectangle in the relationship.
- **destinationRect** Required. The destination rectangle.
Example
In this behavior, all of the sprites have already been set to draggable. Sprite 2b contains a small bitmap. Sprite 1s is a rectangular shape sprite large enough to easily contain sprite 2b. Sprite 4b is a larger version of the bitmap in sprite 2b. Sprite 3s is a larger version of the shape in sprite 1s. Moving sprite 2b or sprite 1s will cause sprite 4b to move. When you drag sprite 2b, its movements are mirrored by sprite 4b. When you drag sprite 1s, sprite 4b moves in the opposite direction. Resizing sprite 2b or sprite 1s will also produce interesting results.

```plaintext
on exitFrame
  sprite(4b).rect = map(sprite(2b).rect, sprite(1s).rect, sprite(3s).rect)
  go the frame
end
```

map (3D)

Usage
```
member(whichCastmember).motion(whichMotion).
  map(whichOtherMotion {}, boneName)
```

Description
3D motion command; maps a specified motion into the current motion, and applies it to a bone and all of the children of that bone. This command replaces any motion previously mapped to the specified bone and its children. This command does not change a model's playlist.

Parameters
- `whichOtherMotion` Required. A string that specifies the name of the motion to map.
- `boneName` Optional. A string that specifies the name of the bone to which the mapped motion is applied. If omitted, the root bone is used.

Example
The following statement maps the motion named LookUp into the motion named SitDown starting from the bone named Neck. The model will sit down and look up at the same time.
```
member("Restaurant").motion("SitDown").map("LookUp", "Neck")
```

See also
- `motion()`, `duration (3D)`, `cloneMotionFromCastmember`
If the specified point on the Stage is not within the sprite, a **VOID** is returned.

**Parameters**

*whichPointInMember* Required. A point from which an equivalent point is returned.

**See also**

map(), mapStageToMember()

**mapStageToMember()**

**Usage**

```
sprite(whichSpriteNumber), mapStageToMember(whichPointOnStage)
mapStageToMember(sprite whichSpriteNumber, whichPointOnStage)
```

**Description**

Function; uses the specified sprite and point to return an equivalent point inside the dimensions of the cast member. This properly accounts for any current transformations to the sprite using *quad*, or the rectangle if not transformed.

This is useful for determining if a particular area on a cast member has been clicked even if there have been major transformations to the sprite on the Stage.

If the specified point on the Stage is not within the sprite, this function returns **VOID**.

**Parameters**

*whichPointOnStage* Required. A point from which an equivalent point is returned.

**See also**

map(), mapMemberToStage()

**marker()**

**Usage**

```
-- Lingo syntax
_movie.marker(markerNameOrNum)

// JavaScript syntax
_movie.marker(markerNameOrNum);
```

**Description**

Movie method; returns the frame number of markers before or after the current frame. This method is useful for implementing a Next or Previous button or for setting up an animation loop.

If the parameter `markerNameOrNum` is an integer, it can evaluate to any positive or negative integer or 0. For example:

- `marker(2)`—Returns the frame number of the second marker after the current frame.
- `marker(1)`—Returns the frame number of the first marker after the current frame.
- `marker(0)`—Returns the frame number of the current frame if the current frame is marked, or the frame number of the previous marker if the current frame is not marked.
• `marker(-1)`—Returns the frame number of the first marker before the marker(0).
• `marker(-2)`—Returns the frame number of the second marker before the marker(0).

If the parameter `markerNameOrNum` is a string, `marker()` returns the frame number of the first frame whose marker label matches the string.

**Parameters**

`markerNameOrNum` **Required.** A string that specifies a marker label, or an integer that specifies a marker number.

**Example**
The following statement sends the playhead to the beginning of the current frame if the current frame has a marker; otherwise, it sends the playhead to the previous marker.

```-- Lingo syntax
_movie.go(_movie.marker(0))
// JavaScript syntax
_movie.go(_movie.marker(0));
```

This statement sets the variable `nextMarker` equal to the next marker in the Score:

```-- Lingo syntax
nextMarker = _movie.marker(1)
// JavaScript syntax
nextMarker = _movie.marker(1);
```

**See also**

`frame`, `frameLabel`, `go()`, `label()`, `markerList`, `Movie`

### max()

**Usage**

```
list.max()
max(list)
max(value1, value2, value3, ...)
```

**Description**

Function (Lingo only); returns the highest value in the specified list or the highest of a given series of values.

The `max` function also works with ASCII characters, similar to the way `<` and `>` operators work with strings.

**Parameters**

`value1, value2, value3, ...` **Optional.** A list of values from which the highest value is chosen.

**Example**
The following handler assigns the variable `Winner` the maximum value in the list `Bids`, which consists of [#Castle:600, #Schmitz:750, #Wang:230]. The result is then inserted into the content of the field cast member Congratulations.
-- Lingo syntax
on findWinner Bids
    Winner = Bids.max()
    member("Congratulations").text = "You have won, with a bid of $" & Winner & "!
end

// JavaScript syntax
function findWinner(Bids) {
    Winner = Bids.max();
    member("Congratulations").text = "You have won, with a bid of $" + 
    Winner + "!";
}

maximize()

Usage
-- Lingo syntax
windowObjRef.maximize()

// JavaScript syntax
windowObjRef.maximize();

Description
Window method; maximizes a window.
Use this method when making custom titlebars.

Parameters
None.

Example
These statements maximize the window named Artists if it is not already maximized.

-- Lingo syntax
if (window("Artists").sizeState <> #maximized) then
    window("Artists").maximize()
end if

// JavaScript syntax
if (window("Artists").sizeState != symbol("maximized")) {
    window("Artists").maximize();
}

See also
minimize(), Window
mci

Usage
mci "string"

Description
Command; for Windows only, passes the strings specified by string to the Windows Media Control Interface (MCI) for control of multimedia extensions.

Note: Microsoft no longer recommends using the 16-bit MCI interface. Consider using third-party Xtra extensions for this functionality instead.

Parameters
string Required. A string that is passed to the MCI.

Example
The following statement makes the command play cdaudio from 200 to 600 track 7 play only when the movie plays back in Windows:
mci "play cdaudio from 200 to 600 track 7"

member()

Usage
-- Lingo syntax
member(memberNameOrNum [, castNameOrNum])

// JavaScript syntax
member(memberNameOrNum [, castNameOrNum]);

Description
Top level function; creates a reference to a cast member, and optionally specifies the cast library that contains the member.

The member() method is a specific reference to both a cast library and a member within it if used with both the memberNameOrNum and castNameOrNum parameters:

trace(sprite(1).member);
// (member 1 of castLib 1)

This method differs from the spriteNum property of a sprite, which is always an integer designating position in a cast library, but does not specify the cast library:

trace(sprite(2).spriteNum);
// 2

The number of a member is also an absolute reference to a particular member in a particular cast library:

trace(sprite(3).member.number)
// 3

Parameters
memberNameOrNum Required. A string that specifies the name of the cast member to reference, or an integer that specifies the index position of the cast member to reference.
**castNameOrNum** Optional. A string that specifies the cast library name to which the member belongs, or an integer that specifies the index position of the cast library to which the member belongs. If omitted, `member()` searches all cast libraries until a match is found.

**Example**

This statement sets the variable `memWings` to the cast member named `Planes`, which is in the cast library named `Transportation`.

```
-- Lingo syntax
memWings = member("Planes", "Transportation")

// JavaScript syntax
var memWings = member("Planes", "Transportation");
```

**See also**

`Member`, `Sprite`, `spriteNum`

### mergeDisplayTemplate()

**Usage**

```
-- Lingo syntax
_movie.mergeDisplayTemplate(propList)

// JavaScript syntax
_movie.mergeDisplayTemplate(propList);
```

**Description**

Movie method; merges an arbitrary number of display template properties into the existing set of display template properties all at once.

**Parameters**

- `propList` Required. A property list that contains the display template properties to merge into the existing set of display template properties. In Lingo, `propList` can be either a comma-separated list of name/value pairs or a comma-separated list of symbol/value pairs. In JavaScript syntax, `propList` can only be a comma-separated list of name/value pairs.

**Example**

This statement merges a value for the `title` property into the `displayTemplate`:

```
-- Lingo syntax
_movie.mergeDisplayTemplate(propList(#title, "Welcome!"))

// JavaScript syntax
_movie.mergeDisplayTemplate(propList("title", "Welcome!"));
```

**See also**

`appearanceOptions`, `displayTemplate`, `Movie`, `propList()`, `titlebarOptions`
mergeProps()

Usage

-- Lingo syntax
windowObjRef.mergeProps(propList)

// JavaScript syntax
windowObjRef.mergeProps(propList);

Description

Windows method. Merges an arbitrary number of window properties, all at once, into the existing set of window properties.

Parameters

propList Required. A set of window properties to merge into the existing set of window properties. The properties are specified by the appearanceOptions and titlebarOptions properties.

• In Lingo, propList can be either a comma-separated list of name/value pairs or a comma-separated list of symbol/value pairs.

• In JavaScript syntax, propList can only be a comma-separated list of name/value pairs.

Example

This statement sets various properties for the window named Cars.

-- Lingo syntax
window("Cars").mergeProps([#title:"Car pictures", #resizable:FALSE, 
   #titlebarOptions:[#closebox:TRUE, #icon:member(2)], 
   #appearanceOptions:[#border:#line, #shadow:TRUE]])

// JavaScript syntax
window("Cars").mergeProps(propList("title","Car pictures", "resizable",false, 
   "titlebarOptions",propList("closebox",true,"icon",member(2)), 
   "appearanceOptions",propList("border","line", "shadow",true)));

See also

appearanceOptions, titlebarOptions, Window

mesh (property)

Usage

member(whichCastmember).model(whichModel).\ 
meshdeform.mesh[index].meshProperty

Description

3D command; allows access to the mesh properties of models that have the meshDeform modifier attached. When used as mesh.count this command returns the total number of meshes within the referenced model.

The properties of each mesh that are accessible are as follows:

• colorList allows you to get or set the list of colors used by the specified mesh.

• vertexList allows you to get or set the list of vertices used by the specified mesh.
- **normalList** allows you to get or set the list of normal vectors used by the specified mesh.
- **textureCoordinateList** allows you to get or set the texture coordinates used by the first texture layer of the specified mesh. To get or set the texture coordinates for any other texture layers in the specified mesh, use `meshDeform.mesh[index].textureLayer[index].textureCoordinateList`.
- **textureLayer[index]** allows you to get and set access to the properties of the specified texture layer.
- **face[index]** allows you to get or set the vertices, normals, texture coordinates, colors, and shaders used by the faces of the specified mesh.
- **face.count** allows you to obtain the total number of faces found within the specified mesh.

**Note:** For complete information about these properties, see the individual entries (listed in the "See also" section of this entry).

**Parameters**
None.

**Example**
The following Lingo adds the `#meshDeform` modifier to the model named thing1 and then displays the vertexList for the first mesh in the model named thing1.

```lingo
member("newAlien").model("thing1").addModifier(#meshDeform)
put member("newAlien").model("thing1").meshDeform.mesh[1].vertexList
```

```text
-- [vector(239.0, -1000.5, 27.4), vector(162.5, -1064.7, 29.3), vector(115.3, -1010.8, -40.6), vector(239.0, -1000.5, 27.4), vector(115.3, -1010.8, -40.6), vector(162.5, -1064.7, 29.3), vector(359.0, -828.5, -46.3), vector(309.9, -914.5, -45.3)]
```

The following statement displays the number of meshes found within the model named "Aircraft".

```lingo
put member("world").model("Aircraft").meshDeform.mesh.count
-- 4
```

**See also**
- `meshDeform (modifier)`, `colorList`, `textureCoordinateList`, `textureLayer`, `normalList`, `vertexList (mesh deform)`, `face[]`

**meshDeform (modifier)**

**Usage**

```lingo
member(whichCastmember).model(whichModel).meshDeform.propertyName
```

**Description**

3D modifier; allows control over the various aspects of the referenced model's mesh structure. Once you have added the `#meshDeform` modifier (using the `addModifier` command) to a model you have access to the following properties of the `#meshDeform` modifier:

**Note:** For more detailed information about the following properties see the individual property entries referenced in the "See also" section of this entry.

- **face.count** returns the total number of faces in the referenced model.
- **mesh.count** returns the number of meshes in the referenced model.
• mesh[index] allows access to the properties of the specified mesh.

Parameters
None.

Example
The following statement displays the number of faces in the model named gbFace:
put member("3D World").model("gbFace").meshDeform.face.count
-- 432

The following statement displays the number of meshes in the model named gbFace:
put member("3D World").model("gbFace").meshDeform.mesh.count
-- 2

The following statement displays the number of faces in the second mesh of the model named gbFace:
put member("3D World").model("gbFace").meshDeform.mesh[2].face.count
-- 204

See also
mesh (property), addModifier

min

Usage
list.min
min(list)
min(a1, a2, a3...)

Description
Function (Lingo only); specifies the minimum value in a list.

Parameters
a1, a2, a3, ... Optional. A list of values from which the lowest value is chosen.

Example
The following handler assigns the variable vLowest the minimum value in the list bids, which
consists of [#Castle:600, #Shields:750, #Wang:230]. The result is then inserted in the content of
the field cast member Sorry:
on findLowest bids
  vLowest = bids.min()
  member("Sorry").text = "We're sorry, your bid of $" & vLowest && "is not a winner!"
end

See also
max()
minimize()

Usage
-- Lingo syntax
windowObjRef.minimize()

// JavaScript syntax
windowObjRef.minimize();

Description
Window method; minimizes a window.
Use this method when making custom titlebars.

Parameters
None.

Example
These statements minimize the window named Artists if it is not already minimized.

-- Lingo syntax
if (window("Artists").sizeState <> #minimized) then
    window("Artists").minimize()
end if

// JavaScript syntax
if (window("Artists").sizeState != symbol("minimized")) {
    window("Artists").minimized();
}

See also
maximize(), Window

model

Usage
member(whichCastmember).model(whichModel)
member(whichCastmember).model[index]
member(whichCastmember).model.count
member(whichCastmember).model(whichModel).propertyName
member(whichCastmember).model[index].propertyName

Description
3D command; returns the model found within the referenced cast member that has the name
specified by whichModel, or is found at the index position specified by index. If no model exists
for the specified parameter, the command returns void. As model.count, the command returns
the number of models found within the referenced cast member. This command also allows
access to the specified model's properties.

Model name comparisons are not case-sensitive. The index position of a particular model may
change when objects at lower index positions are deleted.

If no model is found that uses the specified name or no model is found at the specified index
position then this command returns void.
Parameters

whichModel  Optional. A string that specifies the name of the model to return.

Example

This statement stores a reference to the model named Player Avatar in the variable thismodel:

```
thismodel = member("3DWorld").model("Player Avatar")
```

This statement stores a reference to the eighth model of the cast member named 3DWorld in the variable thismodel:

```
thismodel = member("3DWorld").model[8]
```

This statement shows that there are four models in the member of sprite 1:

```
put sprite(1).member.model.count
-- 4
```

modelResource

Usage

```
member(whichCastmember).modelResource(whichModelResource)
member(whichCastmember).modelResource[index]
member(whichCastmember).modelResource.count
member(whichCastmember).modelResource(whichModelResource).\propertyName
member(whichCastmember).modelResource[index].propertyName
```

Description

3D command; returns the model resource found within the referenced cast member that has the name specified by whichModelResource, or is found at the index position specified by the index parameter. If no model resource exists for the specified parameter, the command returns void. As modelResource.count, the command returns the number of model resources found within the referenced cast member. This command also allows access to the specified model resource’s properties.

Model resource name string comparisons are not case-sensitive. The index position of a particular model resource may change when objects at lower index positions are deleted.

Parameters

whichModelResource  Optional. A string that specifies the name of the model resource to return.

Example

This statement stores a reference to the model resource named HouseA in the variable thismodelResource:

```
thismodelResource = member("3DWorld").modelResource("HouseA")
```

This statement stores a reference to the fourteenth model resource of the cast member named 3DWorld in the variable thismodelResource:

```
thismodelResource = member("3DWorld").modelResource[14]
```

This statement shows that there are ten model resources in the member of sprite 1:

```
put sprite(1).member.modelResource.count
-- 10
```
modelsUnderLoc

Usage

member(whichCastmember).camera(whichCamera).modelsUnderLoc(pointWithinSprite, maxNumberOfModels, levelOfDetail)

Description

3D command; returns a list of models found under a specified point within the rect of a sprite using the referenced camera.

Within the returned list, the first model listed is the one closest to the viewer and the last model listed is the furthest from the viewer.

Only one intersection (the closest intersection) is returned per model.

The command returns an empty list if there are no models found under the specified point.

Parameters

pointWithinSprite Required. A point under which a list of models is found. This point is relative to the upper left corner of the sprite, in pixels.

maxNumberOfModels Optional. An integer that specifies the maximum length of the returned list. If omitted, the command returns a list containing references for all of the models found under the specified point.

levelOfDetail Optional. A symbol that specifies the level of detail of the information returned. Valid values include the following:

• #simple returns a list containing references to the models found under the point. This is the default setting.

• #detailed returns a list of property lists, each representing an intersected model. Each property list will have the following properties:
  ■ #model is a reference to the intersected model object.
  ■ #distance is the distance from the camera to the point of intersection with the model.
  ■ #isectPosition is a vector representing the world space position of the point of intersection.
  ■ #isectNormal is the world space normal vector to the mesh at the point of intersection.
  ■ #meshID is the meshID of the intersected mesh, which can be used as an index into the mesh list of the meshDeform modifier.
  ■ #faceID is the face ID of the intersected face, which can be used as an index into the face list of the meshDeform modifier.
  ■ #vertices is a three-element list of vectors that represent the world space positions of the vertices of the intersected face.
  ■ #uvCoord is a property list with properties #u and #v that represent the u and v barycentric coordinates of the face.
Example

The first line in this handler translates the location of the cursor from a point on the Stage to a point within sprite 5. The second line uses the `modelsUnderLoc` command to obtain the first three models found under that point. The third line displays the returned detailed information about the models in the message window.

```-- Lingo syntax
on mouseUp
    pt = the mouseLoc - point(sprite(5).left, sprite(5).top)
    m = sprite(5).camera.modelsUnderLoc(pt, 3, #detailed)
    put m
end
```

```// JavaScript syntax
function mouseUp()
    pt = _mouse.mouseLoc - point(sprite(5).left, sprite(5).top);
    m = sprite(5).camera.modelsUnderLoc(pt, 3, #detailed);
    put(m);
}
```

See also `modelsUnderRay, modelUnderLoc`

**modelsUnderRay**

**Usage**

```member(whichCastmember).modelsUnderRay(locationVector, directionVector {, maxNumberOfModels, levelOfDetail})```

**Description**

3D command; returns a list of models found under a ray drawn from a specified position and pointing in a specified direction, with both vectors being specified in world-relative coordinates.

Within the returned list, the first model listed is the one closest to the position specified by `locationVector` and the last model listed is the furthest from that position.

Only one intersection (the closest intersection) is returned per model.

The command returns an empty list if there are no models found under the specified ray.

**Parameters**

- `locationVector` Required. A vector from which a ray is drawn and under which a list of models is found.
- `directionVector` Required. A vector that specifies the direction the ray is pointing.
- `maxNumberOfModels` Optional. An integer that specifies the maximum length of the returned list. If omitted, the command returns a list containing references for all of the models found under the specified ray.
- `levelOfDetail` Optional. A symbol that specifies the level of detail of the information returned. Valid values include the following:
  - `#simple` returns a list containing references to the models found under the point. This is the default setting.
• #detailed returns a list of property lists, each representing an intersected model. Each
  property list will have the following properties:
  ■ #model is a reference to the intersected model object.
  ■ #distance is the distance from the world position specified by locationVector to the
    point of intersection with the model.
  ■ #isectPosition is a vector representing the world space position of the point of
    intersection.
  ■ #isectNormal is the world space normal vector to the mesh at the point of intersection.
  ■ #meshID is the meshID of the intersected mesh which can be used to index into the mesh
    list of the meshDeform modifier.
  ■ #faceID is the face ID of the intersected face which can be used to index into the face list of
    the meshDeform modifier.
  ■ #vertices is a 3-element list of vectors that represent the world space positions of the
    vertices of the intersected face.
  ■ #uvCoord is a property list with properties #u and #v that represent the u and v barycentric
    coordinates of the face.

Example

This statement displays the detailed information for a model intersected by a ray drawn from the
position vector (0, 0, 300) and pointing down the -z axis:
put member("3d").modelsUnderRay(vector(0, 0, 300), vector(0, 0, -1), 3, #detailed)
-- [[#model: model("mSphere"), #distance: 275.0000, 
  #isectPosition: vector( 0.0000, 0.0000, 25.0000 ), #isectNormal: 
  vector( -0.0775, 0.0161, 0.9969 ), #meshID: 1, #faceID: 229, 
  #vertices: [vector( 0.0000, 0.0000, 25.0000 ), vector( -3.6851, 
  1.3097, 24.6922 ), vector( -3.9017, 0.2669, 24.6922 )], 
  #uvCoord: [#u: 0.0000, #v: 0.0000]]

See also
  modelsUnderLoc, modelUnderLoc

modelUnderLoc

Usage
  member(whichCastmember).camera(whichCamera).
  modelUnderLoc(pointWithinSprite)

Description

3D command; returns a reference to the first model found under a specified point within the rect
of a sprite using the referenced camera.

This command returns void if there is no model found under the specified point.

For a list of all of the models found under a specified point, and detailed information about them,
see modelsUnderLoc.

Parameters

  pointWithinSprite Required. A point under which the first model is found. The location of
  pointWithinSprite is relative to the upper left corner of the sprite, in pixels.
Example

The first line in this handler translates the location of the cursor from a point on the Stage to a point within sprite 5. The second line determines the first model under that point. The third line displays the result in the message window.

-- Lingo syntax
on mouseUp
  pt = the mouseLoc - point(sprite(5).left, sprite(5).top)
  m = sprite(5).camera.modelUnderLoc(pt)
  put m
end

// JavaScript syntax
function mouseUp() {
  pt = _mouse.mouseLoc - point(sprite(5).left, sprite(5).top);
  m = sprite(5).camera.modelUnderLoc(pt);
  put(m);
}

See also

modelsUnderLoc, modelsUnderRay

motion()

Usage

member(whichCastmember).motion(whichMotion)
member(whichCastmember).motion[index]
member(whichCastmember).motion.count

Description

3D command; returns the motion found within the referenced cast member that has the name specified by whichMotion, or is found at the index position specified by the index. As motion.count, this property returns the total number of motions found within the cast member.

Object name string comparisons are not case-sensitive. The index position of a particular motion may change when objects at lower index positions are deleted.

If no motion is found that uses the specified name or no motion is found at the specified index position then this command returns void.

Example

thisMotion = member("3D World").motion("Wing Flap")
thisMotion = member("3D World").motion[7]
put member("scene").motion.count
  -- 2

See also

duration (3D), map (3D)
move()

Usage
-- Lingo syntax
memberObjRef.move({intPosn, castLibName})

// JavaScript syntax
memberObjRef.move({intPosn, castLibName});

Description
Member method; moves a specified cast member to either the first empty location in its containing cast, or to a specified location in a given cast.

For best results, use this method during authoring, not at runtime, because the move is typically saved with the file. The actual location of a cast member does not affect most presentations during playback for an end user. To switch the content of a sprite or change the display during runtime, set the member of the sprite.

Parameters
intPosn Optional. An integer that specifies the position in the cast library castLibName to which the member is moved.

castLibName Optional. A string that specifies the name of the cast library to which the member is moved.

Example
This statement moves cast member Shrine to the first empty location in the Cast window:
-- Lingo syntax
member("shrine").move()

// JavaScript syntax
member("shrine").move();

This statement moves cast member Shrine to location 20 in the Bitmaps Cast window:
-- Lingo syntax
member("shrine").move(20, "Bitmaps")

// JavaScript syntax
member("shrine").move(20, "Bitmaps");

See also
Member

moveToBack()

Usage
-- Lingo syntax
windowObjRef.moveToBack()

// JavaScript syntax
windowObjRef.moveToBack();

Description
Window method; moves a window behind all other windows.
Parameters
None.

Example
These statements move the first window in windowList behind all other windows:

-- Lingo syntax
myWindow = _player.windowList[1]
myWindow.moveToBack()

// JavaScript syntax
var myWindow = _player.windowList[1];
myWindow.moveToBack();

If you know the name of the window you want to move, use the syntax:

-- Lingo syntax
window("Demo Window").moveToBack()

// JavaScript syntax
window("Demo Window").moveToBack();

See also
moveToFront(), Window

moveToFront()

Usage
-- Lingo syntax
windowObjRef.moveToFront()

// JavaScript syntax
windowObjRef.moveToFront();

Description
Window method; moves a window in front of all other windows.

Parameters
None.

Example
These statements move the first window in windowList in front of all other windows:

-- Lingo syntax
myWindow = _player.windowList[1]
myWindow.moveToFront()

// JavaScript syntax
var myWindow = _player.windowList[1];
myWindow.moveToFront();

If you know the name of the window you want to move, use the syntax:

-- Lingo syntax
window("Demo Window").moveToBack()
// JavaScript syntax
window("Demo Window").moveToFront();

See also
moveToBack(), Window

moveVertex()

Usage

-- Lingo syntax
memberObjRef.moveVertex(vertexIndex, xChange, yChange)

// JavaScript syntax
memberObjRef.moveVertex(vertexIndex, xChange, yChange);

Description
Function; moves the vertex of a vector shape cast member to another location.

The horizontal and vertical coordinates for the move are relative to the current position of the vertex point. The location of the vertex point is relative to the origin of the vector shape member.

Changing the location of a vertex affects the shape in the same way as dragging the vertex in an editor.

Parameters

vertexIndex Required. Specifies the index position of the vertex to move.
xChange Required. Specifies the amount to move the vertex horizontally.
yChange Required. Specifies the amount to move the vertex vertically.

Example

This statement shifts the first vertex point in the vector shape Archie 25 pixels to the right and 10 pixels down from its current position:

-- Lingo syntax
member("Archie").moveVertex(1, 25, 10)

// JavaScript syntax
member("Archie").moveVertex(1, 25, 10);

See also
addVertex(), deleteVertex(), moveVertexHandle(), originMode, vertexList

moveVertexHandle()

Usage

-- Lingo syntax
memberObjRef.moveVertexHandle(vertexIndex, handleIndex, xChange, yChange)

// JavaScript syntax
memberObjRef.moveVertexHandle(vertexIndex, handleIndex, xChange, yChange);

Description
Function; moves the vertex handle of a vector shape cast member to another location.
The horizontal and vertical coordinates for the move are relative to the current position of the vertex handle. The location of the vertex handle is relative to the vertex point it controls. Changing the location of a control handle affects the shape in the same way as dragging the vertex in the editor.

**Parameters**

- `vertexIndex` Required. Specifies the index position of the vertex that contains the handle to move.
- `handleIndex` Required. Specifies the index position of the handle to move.
- `xChange` Required. Specifies the amount to move the vertex handle horizontally.
- `yChange` Required. Specifies the amount to move the vertex handle vertically.

**Example**

This statement shifts the first control handle of the second vertex point in the vector shape Archie 15 pixels to the right and 5 pixels up:

```-- Lingo syntax
moveVertexHandle(member("Archie"), 2, 1, 15, -5)
// JavaScript syntax
moveVertexHandle(member("Archie"), 2, 1, 15, -5)
```

**See also**

- `addVertex()`, `deleteVertex()`, `originMode`, `vertexList`
- `multiply()`

**multiply()**

**Usage**

`transform.multiply(transform2)`

**Description**

3D command; applies the positional, rotational, and scaling effects of `transform2` after the original transform.

**Parameters**

- `transform2` Required. Specifies the transform that contains the effects to apply to another transform.

**Example**

This statement applies the positional, rotational, and scaling effects of the model Mars's transform to the transform of the model Pluto. This has a similar effect as making Mars be Pluto's parent for a frame.

```member("scene").model("Pluto").transform.multiply(member("scene")\ .model("Mars").transform)```
neighbor

Usage

\[
\text{member}(\text{whichCastmember}).\text{model}(\text{whichModel}).\text{mesh\texttt{deform}}.\text{mesh}[\text{index}].\backslash \\
\text{face}[\text{index}].\text{neighbor}[\text{index}]
\]

Description

3D command; mesh\texttt{deform} command that returns a list of lists describing the neighbors of a particular face of a mesh opposite the face corner specified by the neighbor index \((1,2,3)\). If the list is empty, the face has no neighbors in that direction. If the list contains more than one list, the mesh is non-manifold. Usually the list contains a single list of four integer values: \([\text{meshIndex}, \text{faceIndex}, \text{vertexIndex}, \text{flipped}]\).

The value \text{meshIndex} is the index of the mesh containing the neighbor face. The value \text{faceIndex} is the index of the neighbor face in that mesh. The value \text{vertexIndex} is the index of the nonshared vertices of the neighbor face. The value \text{flipped} describes whether the face orientation is the same as (1) or opposite (2) that of the original face.

Parameters

None.

See also

\begin{itemize}
  \item mesh\texttt{deform} \texttt{(modifier)}
\end{itemize}

netAbort

Usage

\[
\text{netAbort}(\text{URL})
\]

\[
\text{netAbort}(\text{netID})
\]

Description

Command; cancels a network operation without waiting for a result.

Using a network ID is the most efficient way to stop a network operation. The ID is returned when you use a network function such as \texttt{getNetText()} or \texttt{postNetText()}. In some cases, when a network ID is not available, you can use a URL to stop the transmission of data for that URL. The URL must be identical to that used to begin the network operation. If the data transmission is complete, this command has no effect.

Parameters

\[
\begin{itemize}
  \item \text{URL} Required. Specifies the URL to cancel.
  \item \text{netID} Optional. Specifies the ID of the network operation to cancel.
\end{itemize}
\]
Example

This statement passes a network ID to netAbort to cancel a particular network operation:

```
-- Lingo syntax
on mouseUp
    netAbort(myNetID)
end

// JavaScript syntax
function mouseUp()

    netAbort(myNetID);

```

See also

```
getNetText(), postNetText
```

netDone()

Usage

```
netDone()
netDone(netID)
```

Description

Function; indicates whether a background loading operation (such as getNetText, preloadNetThing, gotoNetMovie, gotoNetPage, or netTextResult) is finished or was terminated by a browser error (TRUE, default) or is still in progress (FALSE).

- Use netDone() to test the last network operation.
- Use netDone(netID) to test the network operation identified by netID.

The netDone function returns 0 when a background loading operation is in progress.

Parameters

```
netID Optional. Specifies the ID of the network operation to test.
```

Example

The following handler uses the netDone function to test whether the last network operation has finished. If the operation is finished, text returned by netTextResult is displayed in the field cast member Display Text.

```
-- Lingo syntax
on exitFrame
    if netDone() = 1 then
        member("Display Text").text = netTextResult()
    end if
end

// JavaScript syntax
function exitFrame()

    if (netDone() == 1) {
        member("Display Text").text = netTextResult();
    }
```

```
This handler uses a specific network ID as an argument for `netDone` to check the status of a specific network operation:

```
-- Lingo syntax
on exitFrame
    -- stay on this frame until the net operation is completed
    global mynetID
    if netDone(mynetID) = FALSE then
go to the frame
    end if
end

// JavaScript syntax
function exitFrame() {
    // stay on this frame until the net operation is completed
    global mynetID;
    if (!(netDone(mynetID))) {
        _movie.go(_movie.frame);
    }
}
```

See also `getNetText()`, `netTextResult()`, `gotoNetMovie`, `preloadNetThing()`

**netError()**

**Usage**

`netError()`  
`netError(netID)`

**Description**

Function; determines whether an error has occurred in a network operation and, if so, returns an error number corresponding to an error message. If the operation was successful, this function returns a code indicating that everything is okay. If no background loading operation has started, or if the operation is in progress, this function returns an empty string.

- Use `netError()` to test the last network operation.  
- Use `netError(netID)` to test the network operation specified by netID.

Several possible error codes may be returned:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Everything is okay.</td>
</tr>
<tr>
<td>4</td>
<td>Bad MOA class. The required network or nonnetwork Xtra extensions are improperly installed or not installed at all.</td>
</tr>
<tr>
<td>5</td>
<td>Bad MOA Interface. See 4.</td>
</tr>
<tr>
<td>6</td>
<td>Bad URL or Bad MOA class. The required network or nonnetwork Xtra extensions are improperly installed or not installed at all.</td>
</tr>
<tr>
<td>20</td>
<td>Internal error. Returned by <code>netError()</code> in the Netscape browser if the browser detected a network or internal error.</td>
</tr>
<tr>
<td>4146</td>
<td>Connection could not be established with the remote host.</td>
</tr>
<tr>
<td>4149</td>
<td>Data supplied by the server was in an unexpected format.</td>
</tr>
</tbody>
</table>
Parameters

netID Optional. Specifies the ID of the network operation to test.

Example

This statement passes a network ID to netError to check the error status of a particular network operation:

-Lingo syntax
on exitFrame
    global mynetID
    if netError(mynetID)<"OK" then beep
end

// JavaScript syntax
function exitFrame() {
    global mynetID;
    if (netError(mynetID) != "OK") {
        _sound.beep();
    }
}

netLastModDate()

Usage
netLastModDate()

Description

Function; returns the date last modified from the HTTP header for the specified item. The string is in Universal Time (GMT) format: Ddd, nn MMM yyyy hh:mm:ss GMT (for example, Thu, 30 Jan 1997 12:00:00 AM GMT). There are variations where days or months are spelled completely. The string is always in English.
The `netLastModDate` function can be called only after `netDone` and `netError` report that the operation is complete and successful. After the next operation starts, the Director movie or projector discards the results of the previous operation to conserve memory.

The actual date string is pulled directly from the HTTP header in the form provided by the server. However, this string is not always provided, and in that case `netLastModDate` returns `EMPTY`.

**Parameters**

None.

**Example**

These statements check the date of a file downloaded from the Internet:

```lingo
-- Lingo syntax
if netDone() then
    theDate = netLastModDate()
    if theDate.char[6..11] <> "Jan 30" then
        alert "The file is outdated."
    end if
end if
```

```javascript
// JavaScript syntax
if (netDone()) {
    theDate = netLastModDate();
    if (theDate.char[6..11] != "Jan 30") {
        alert("The file is outdated");
    }
}
```

**See also**

`netDone()`, `netError()`

---

**netMIME()**

**Usage**

netMIME()

**Description**

Function; provides the MIME type of the Internet file that the last network operation returned (the most recently downloaded HTTP or FTP item).

The `netMIME` function can be called only after `netDone` and `netError` report that the operation is complete and successful. After the next operation starts, the Director movie or projector discards the results of the previous operation to conserve memory.

**Parameters**

None.
Example

This handler checks the MIME type of an item downloaded from the Internet and responds accordingly:

```-- Lingo syntax
on checkNetOperation theURL
    if netDone (theURL) then
        set myMimeType = netMIME()
        case myMimeType of
            "image/jpeg": go frame "jpeg info"
            "image/gif": go frame "gif info"
            "application/x-director": goToNetMovie theURL
            "text/html": goToNetPage theURL
            otherwise: alert "Please choose a different item."
        end case
    else
        go the frame
    end if
end

// JavaScript syntax
function checkNetOperation(theURL) {
    if (netDone(theURL)) {
        myMimeType = netMIME();
        switch (myMimeType) {
            case "image/jpeg":
                _movie.go("jpeg info");
                break;
            case "image/gif":
                _movie.go("gif info");
                break;
            case "application/x-director":
                goToNetMovie(theURL);
                break;
            case "text/html":
                goToNetPage(theURL);
                break;
            default:
                alert("Please choose a different item.");
        }
    } else {
        _movie.go(_movie.frame);
    }
}
```

See also

`netDone()`, `netError()`, `getNetText()`, `postNetText`, `preloadNetThing()`

**netStatus**

**Usage**

`netStatus msgString`

**Description**

Command; displays the specified string in the status area of the browser window. The `netStatus` command doesn't work in projectors.
Parameters

msgString Required. Specifies the string to display.

Example

This statement would place the string “This is a test” in the status area of the browser the movie is running in:

```-- Lingo syntax
on exitFrame
  netStatus "This is a test"
end

// JavaScript syntax
function exitFrame() {
  _movie.netStatus("This is a test");
}
```

netTextResult()

Usage

netTextResult(netID)

netTextResult()

Description

Function; returns the text obtained by the specified network operation. If no net ID is specified, netTextResult returns the result of the last network operation.

If the specified network operation was getNetText(), the text is the text of the file on the network.

If the specified network operation was postNetText, the result is the server’s response.

After the next operation starts, Director discards the results of the previous operation to conserve memory.

When a movie plays back as an applet, this function returns valid results for the last 10 requests. When a movie plays back as a movie with Shockwave content, this function returns valid results for only the most recent getNetText() operation.

Parameters

netID Optional. Specifies the ID of the network operation that contains the text to return.

Example

This handler uses the “netDone and netError” functions to test whether the last network operation finished successfully. If the operation is finished, text returned by netTextResult is displayed in the field cast member Display Text.

```-- Lingo syntax
global gNetID

on exitFrame
  if (netDone(gNetID) = TRUE) and (netError(gNetID) = "OK") then
    member("Display Text").text = netTextResult()
  end if
end```
// JavaScript syntax

```javascript
function exitFrame() {
  if (netDone(gNetID) && (netError(gNetID) == "OK")) {
    member("Display Text").text = netTextResult();
  }
}
```

See also

```
netDone(), netError(), postNetText
```

**new()**

**Usage**

```
new(type)
new(type, castLib whichCast)
new(type, member whichCastMember of castLib whichCast)
variableName = new(parentScript arg1, arg2, ...)
new(script parentScriptName, value1, value2, ...)
timeout("name").new(timeoutPeriod, #timeoutHandler, [, targetObject])
new(xtra "xtraName")
```

**Description**

Function; creates a new cast member, child object, timeout object, or Xtra instance and allows you to assign of individual property values to child objects.

For cast members, the `type` parameter sets the cast member's type. Possible predefined values correspond to existing cast member types: `#bitmap`, `#field`, and so on. The `new` function can also create Xtra cast member types, which can be identified by any name that the author chooses.

It's also possible to create a new color cursor cast member using the Custom Cursor Xtra. Use `new(#cursor)` and set the properties of the resulting cast member to make them available for use.

The optional `whichCastMember` and `whichCast` parameters specify the cast member slot and Cast window where the new cast member is stored. When no cast member slot is specified, the first empty slot is used. The `new` function returns the cast member slot.

When the argument for the `new` function is a parent script, the `new` function creates a child object. The parent script should include an `on new` handler that sets the child object's initial state or property values and returns the `me` reference to the child object.

The child object has all the handlers of the parent script. The child object also has the same property variable names that are declared in the parent script, but each child object has its own values for these properties.

Because a child object is a value, it can be assigned to variables, placed in lists, and passed as a parameter.

As with other variables, you can use the `put` command to display information about a child object in the Message window.

When `new()` is used to create a timeout object, the `timeoutPeriod` sets the number of milliseconds between timeout events sent by the timeout object. The `#timeoutHandler` is a symbol that identifies the handler that will be called when each timeout event occurs. The `targetObject` identifies the name of the child object that contains the `#timeoutHandler`. If no `targetObject` is given, the `#timeoutHandler` is assumed to be in a movie script.
When a timeout object is created, it enables its targetObject to receive the system events prepareMovie, startMovie, stopMovie, prepareFrame, and exitFrame. To take advantage of this, the targetObject must contain handlers for these events. The events do not need to be passed in order for the rest of the movie to have access to them.

To see an example of new() used in a completed movie, see the Parent Scripts, and Read and Write Text movies in the Learning/Lingo folder inside the Director application folder.

Example

To create a new bitmap cast member in the first available slot, you use this syntax:

```lingo
set newMember = new(#bitmap)
```

After the line has been executed, newMember will contain the member reference to the cast member just created:

```lingo
put newMember
-- (member 1 of castLib 1)
```

The following startMovie script creates a new Flash cast member using the new command, sets the newly created cast member's linked property so that the cast member's assets are stored in an external file, and then sets the cast member's pathName property to the location of a Flash movie on the World Wide Web:

```lingo
on startMovie
  flashCastMember = new(#flash)
  member(flashCastMember).pathName = "http://www.someURL.com/myFlash.swf"
end
```

When the movie starts, this handler creates a new animated color cursor cast member and stores its cast member number in a variable called customCursor. This variable is used to set the castMemberList property of the newly created cursor and to switch to the new cursor.

```lingo
on startmovie
  customCursor = new(#cursor)
  member(customCursor).castMemberList = [member 1, member 2, member 3]
  cursor (member(customCursor))
end
```

These statements from a parent script include the on new handler to create a child object. The parent script is a script cast member named Bird, which contains these handlers.

```lingo
on new me, nameForBird
  return me
end

on fly me
  put "I am flying"
end
```

The first statement in the following example creates a child object from the above script in the preceding example, and places it in a variable named myBird. The second statement makes the bird fly by calling the fly handler in the Bird parent script:

```lingo
myBird = script("Bird").new()
myBird.fly()
```
This statement uses a new Bird parent script, which contains the property variable `speed`:

```plaintext
property speed

on new me, initSpeed
    speed = initSpeed
    return me
end

on fly me
    put "I am flying at " & speed & " mph"
end
```

The following statements create two child objects called `myBird1` and `myBird2`. They are given different starting speeds: 15 and 25, respectively. When the `fly` handler is called for each child object, the speed of the object is displayed in the Message window:

```plaintext
myBird1 = script("Bird").new(15)
myBird2 = script("Bird").new(25)
myBird1.fly()
myBird2.fly()
```

This message appears in the Message window:

```
-- "I am flying at 15 mph"
-- "I am flying at 25 mph"
```

This statement creates a new timeout object called `intervalTimer` that will send a timeout event to the `on minuteBeep` handler in the child object `playerOne` every 60 seconds:

```plaintext
timeout("intervalTimer").new(60000, #minuteBeep, playerOne)
```

- `on stepFrame`, `actorList`, `ancestor`, `me`, `type (Member)`, `timeout()`

### newCamera

**Usage**

```plaintext
member(whichCastmember).newCamera(newCameraName)
```

**Description**

3D command; creates a new camera within a cast member.

**Parameters**

- `newCameraName` **Required.** Specifies the name of the new camera. The name of the new camera must be unique within the cast member.

**Example**

This statement creates a new camera called in-car camera:

```plaintext
member("3D World").newCamera("in-car camera")
```
newCurve()

Usage
-- Lingo syntax
memberObjRef.newCurve(positionInVertexList)

// JavaScript syntax
memberObjRef.newCurve(positionInVertexList);

Description
Function; adds a newCurve symbol to the vertexList of vectorCastMember, which adds a new shape to the vector shape. You can break apart an existing shape by calling newCurve() with a position in the middle of a series of vertices.

Parameters

positionInVertexList Required. Specifies the position in the vertexList at which the newCurve symbol is added.

Example
These statements add a new curve to cast member 2 at the third position in the cast member's vertexList. The second line of the example replaces the contents of curve 2 with the contents of curve 3.

-- Lingo syntax
member(2).newCurve(3)

// JavaScript syntax
member(2).newCurve(3);
member(2).curve[2] = member(2).curve[3];

See also
curve, vertexList

newGroup

Usage
member(whichCastmember).newGroup(newGroupName)

Description
3D command; creates a new group and adds it to the group palette.

Parameters

newGroupName Required. Specifies the name of the new group. The name of the new group must be unique within the group palette.

Example
This statement creates a group called gbGroup2 within the cast member Scene, and a reference to it is stored in the variable ng:

ng = member("Scene").newGroup("gbGroup2")
newLight

Usage
member(whichCastmember).newLight(newLightName, #typeIndicator)

Description
3D command; creates a new light with a specified type, and adds it to the light palette.

Parameters
newLightName Required. Specifies the name of the new light. The name of the new light must be unique within the light palette.

typeIndicator Required. A symbol that specifies the type of the new light. Valid values include the following:
• #ambient is a generalized light in the 3D world.
• #directional is a light from a specific direction.
• #point is a light source like a light bulb.
• #spot is a spotlight effect.

Example
The following statement creates a new light in the cast member named 3D World. It is an ambient light called "ambient room light".
member("3D World").newLight("ambient room light", #ambient)

newMember()

Usage
-- Lingo syntax
_movie.newMember(symbol)
_movie.newMember(stringMemberType)

// JavaScript syntax
_movie.newMember(stringMemberType);

Description
Movie method; creates a new cast member and allows you to assign individual property values to child objects.

For new cast members, the symbol or stringMemberType parameter sets the cast member's type. Possible predefined values correspond to the existing cast member types: #bitmap, #field, and so on. The newMember() method can also create Xtra cast member types, which can be identified by any name that the author chooses.

It's also possible to create a new color cursor cast member using the Custom Cursor Xtra. Use newMember(#cursor) and set the properties of the resulting cast member to make them available for use.

After newMember() is called, the new cast member is placed in the first empty cast library slot.
When the argument for the `new()` function is a parent script, the `new` function creates a child object. The parent script should include an `on new` handler that sets the child object's initial state or property values and returns the `me` reference to the child object.

The child object has all the handlers of the parent script. The child object also has the same property variable names that are declared in the parent script, but each child object has its own values for these properties.

Because a child object is a value, it can be assigned to variables, placed in lists, and passed as a parameter.

As with other variables, you can use the `put()` method to display information about a child object in the Message window.

When `new()` is used to create a timeout object, the `timeoutPeriod` sets the number of milliseconds between timeout events sent by the timeout object. The `#timeoutHandler` is a symbol that identifies the handler that will be called when each timeout event occurs. The `targetObject` identifies the name of the child object that contains the `#timeoutHandler`. If no `targetObject` is given, the `#timeoutHandler` is assumed to be in a movie script.

When a timeout object is created, it enables its `targetObject` to receive the system events `prepareMovie`, `startMovie`, `stopMovie`, `prepareFrame`, and `exitFrame`. To take advantage of this, the `targetObject` must contain handlers for these events. The events do not need to be passed in order for the rest of the movie to have access to them.

To see an example of `newMember()` used in a completed movie, see the Parent Scripts, and Read and Write Text movies in the Learning/Lingo folder inside the Director application folder.

**Parameters**

- `symbol` (Lingo only) Required. A symbol that specifies the type of the new cast member.
- `stringMemberType` Required. A string that specifies the type of the new cast member.

**Example**

The following statements create a new bitmap cast member and assign it to the variable `newBitmap`.

```lang
-- Lingo syntax
newBitmap = _movie.newMember(#bitmap) -- using a symbol
newBitmap = _movie.newMember("bitmap") -- using a string

// JavaScript syntax
var newBitmap = _movie.newMember("bitmap");
```

**See also**

- `Movie`, `type (Member)`
newMesh

Usage

member(whichCastmember).newMesh(name,numFaces, numVertices,
numNormals,numColors,numTextureCoordinates)

Description

3D command; creates a new mesh model resource. After creating a mesh, you must set values for
at least the vertexList and face[index].vertices properties of the new mesh, followed by a
call to its build() command, in order to actually generate the geometry.

Parameters

meshName Required. Specifies the name of the new mesh model resource.

numFaces Required. Specifies the desired total number of triangles you want in the mesh.

numVertices Required. Specifies the total number of vertices used by all the (triangular) faces. A
vertex may be shared by more than one face.

numNormals Optional. Specifies the total number of normals. A normal may be shared by more
than one face. The normal for a corner of a triangle defines which direction is outward, affecting
how that corner is illuminated by lights. Enter 0 or omit this parameter if you are going to use the
mesh's generateNormals() command to generate normals.

numColors Optional. Specifies the total number of colors used by all the faces. A color may be
shared by more than one face. You can specify a color for each corner of each face. Specify colors
for smooth color gradation effects. Enter 0 or omit this parameter to get default white color per
face corner.

numTextureCoordinates Optional. Specifies the number of user-specified texture coordinates
used by all the faces. Enter 0 or omit this parameter to get the default texture coordinates
generated via a planar mapping. (See the explanation of #planar in the
shader.textureWrapMode entry for more details). Specify texture coordinates when you need
precise control over how textures are mapped onto the faces of the mesh.

Example

This example creates a model resource of the type #mesh, specifies its properties, and then creates
a new model from the model resource. The process is outlined in the following line-by-line
explanation of the example code:

Line 1 creates a mesh containing 6 faces, composed of 5 unique vertices and 3 unique colors. The
number of normals and the number of textureCoordinates are not set. The normals will be
created by the generateNormals command.

Line 2 defines the five unique vertices used by the faces of the mesh.

Line 3 defines the three unique colors used by the faces of the mesh.

Lines 4 through 9 assign which vertices to use as the corners of each face in the Pyramid. Note
the clockwise ordering of the vertices. GenerateNormals() relies on a clockwise ordering.

Lines 10 through 15 assign colors to the corners of each face. The colors will spread across the
faces in gradients.

Line 16 creates the normals of Triangle by calling the generateNormals() command.
Line 17 calls the build command to construct the mesh.

```
nm = member("Shapes").newMesh("pyramid", 6, 5, 0, 3)
nm.vertexList = [vector(0,0,0), vector(40,0,0),
                 vector(40,0,40), vector(0,0,40), vector(20,50,20)]
nm.colorList = [rgb(255,0,0), rgb(0,255,0), rgb(0,0,255)]
nm.face[1].vertices = [4,1,2]
nm.face[2].vertices = [4,2,3]
nm.face[3].vertices = [5,2,1]
nm.face[4].vertices = [5,3,2]
nm.face[5].vertices = [5,4,3]
nm.face[6].vertices = [5,1,4]
nm.face[1].colors = [3,2,3]
nm.face[2].colors = [3,3,2]
nm.face[3].colors = [1,3,2]
nm.face[4].colors = [1,2,3]
nm.face[5].colors = [1,3,2]
nm.face[6].colors = [1,2,3]
nm.generateNormals(#flat)
nm.build()
```

See also

newModelResource

newModel

Usage

```
member( whichCastmember ),newModel( newModelName \n   , whichModelResource )
```

Description

3D command; creates a new model in the referenced cast member. All new models have their resource property set to VOID by default.

Parameters

- **newModelName** Required. Specifies the name of the new model. The name of the new model must be unique.
- **whichModelResource** Optional. Specifies a model resource to create the model from.

Example

This statement creates a model called New House within the cast member 3D World.

```
member("3D World").newModel("New House")
```

Alternatively, the model resource for the new model can be set with the optional parameter.

```
member("3D World").newModel("New House", member("3D World").modelResource("bigBox"))
```
newModelResource

Usage
member(whichCastmember).newModelResource(newModelResourceName \n   i .#type, #facing )

Description
3D command; creates a new model resource, optionally of a give type and facing, and adds it to
the model resource palette.

If you do not choose to specify the facing parameter and specify #box,#sphere,#particle or
#cylinder for the type parameter, only the front faces are generated. If you specify #plane, both
the front and back faces are generated. Model resources of the type #plane have two meshes
generated (one for each side), and consequently has two shaders in the shaderList.

A facing of #both creates the double amount of meshes and consequently produces double the
number of shader entries in the shaderList. There will be 2 for planes and spheres (for the inside
and outside of the model respectively), 12 for cubes (6 on the outside, 6 on the inside), and 6 for
cylinders (top, hull and bottom outside, and another set for the inside).

Parameters
newModelResourceName Required. Specifies the name of the new model resource.
type Optional. Specifies the primitive type of the new model resource. Valid values are as follows:
• #plane
• #box
• #sphere
• #cylinder
• #particle
facing Optional. Specifies the face of the new model resource. Valid values are as follows:
• #front
• #back
• #both

Example
The following handler creates a box. The first line of the handler creates a new model resource
called box10. Its type is #box, and it is set to show only its back. The next three lines set the
dimensions of box10 and the last line creates a new model which uses box10 as its model
resource.

on makeBox
  nmr = member("3D").newModelResource("box10", #box, #back)
nmr.height = 50
nmr.width = 50
nmr.length = 50
aa = member("3D").newModel("gb5", nmr)
end
This statement creates a box-shaped model resource called hatbox4.

```
member("Shelf").newModelResource("hatbox4", #box)
```

**See also**
primitives

### newMotion()

**Usage**

```
member(whichCastmember).newMotion(name)
```

**Description**

3D command; creates a new motion within a referenced cast member, and returns a reference to the new motion. A new motion can be used to combine several previously existing motions from the member's motion list via the `map()` command.

**Parameters**

- `name` Required. Specifies the name of the new motion. The name of the new motion must be unique within the referenced cast member.

**Example**

This Lingo creates a new motion in member 1 called `runWithWave` that is used to combine the run and wave motions from the member's motion list:

```
runWithWave = member(1).newMotion("runWithWave")
runWithWave.map("run", "pelvisBone")
runWithWave.map("wave", "shoulderBone")
```

### newObject()

**Usage**

- **Lingo syntax**

  ```
  spriteObjRef.newObject(objectType {, arg1, arg2 ....})
  ```

- **JavaScript syntax**

  ```
  SpriteObjRef.newObject(objectType {, arg1, arg2 ....});
  ```

**Description**

Flash sprite command; creates an ActionScript object of the specified type.

The following syntax creates an object within a Flash sprite:

```
flashSpriteReference.newObject("objectType" {, arg1, arg2 ....})
```

The following syntax creates a global object:

```
newObject("objectType" {, arg1, arg2 ....})
```

**Note:** If you have not imported any Flash cast members, you must manually add the Flash Asset Xtra to your movie’s Xtra list in order for global Flash commands to work correctly in the Shockwave Player and projectors. You add Xtra extensions to the Xtra list by choosing Modify > Movie > Xtras. For more information about managing Xtra extensions for distributed movies, see the Using Director topics in the Director Help Panel.
Parameters

objectType Required. Specifies the type of new object to create.
arg1, arg2, ... Optional. Specifies any initialization arguments required by the object. Each argument must be separated by a comma.

Example

This Lingo sets the variable tLocalConObject to a reference to a new LocalConnection object in the Flash movie in sprite 3:

-- Lingo syntax
tLocalConObject = sprite(3).newObject("LocalConnection")

// JavaScript syntax
var tLocalConObject = sprite(3).newObject("LocalConnection");

The following Lingo sets the variable tArrayObject to a reference to a new array object in the Flash movie in sprite 3. The array contains the 3 integer values 23, 34, and 19.

-- Lingo syntax
tArrayObject = sprite(3).newObject("Array",23,34,19)

// JavaScript syntax
var tArrayObject = sprite(3).newObject("Array",23,34,19);

setCallback(), clearAsObjects()

newShader

Usage
member(whichCastmember).newShader(newShaderName, #shaderType)

Description

3D command; creates a new shader of a specified shader type within a referenced cast member's shader list and returns a reference to the new shader.

Each type of shader has a specific group of properties that can be used with that type of shader, in addition all shader types have access to the #standard shader properties. However, although you can assign any #standard shader property to a shader of another type, the property may not have a visual effect. This happens in cases where the #standard property, if applied, would override the nature of the shader type. An example of this is the diffuseLightMap #standard shader property, which is ignored by #engraver, #newsprint, and #painter type shaders.
### Parameters

**newShaderName** Required. Specifies the name of the new shader. The name of the new shader must be unique in the shader list.

**shaderType** Required. A symbol that determines the style in which the shader is applied. Valid values include the following:

- **#standard** shaders are photorealistic, and have the following properties: ambient, blend, blendConstant, blendConstantList, blendFunction, blendFunctionList, blendSource, blendSourceList, diffuse, diffuseLightMap, emissive, flat, glossMap, ilk, name, region, renderStyle, silhouettes, specular, specularLightMap, texture, textureMode, textureModelList, textureRepeat, textureRepeatList, textureTransform, textureTransformList, transparent, useDiffuseWithTexture, wrapTransform, and wrapTransformList.
- **#painter** shaders are smoothed out, have the appearance of a painting, and have the following properties in addition to all of the #standard properties: colorSteps, hilightPercentage, hilightStrength, name, shadowPercentage, shadowStrength, and style.
- **#engraver** shaders are lined, have the appearance of an engraving, and have the following properties in addition to all of the #standard properties: brightness, density, name, and rotation.
- **#newsprint** shaders are in a simulated dot style, have the appearance of a newspaper reproduction, and have the following properties in addition to all of the #standard properties: brightness, density, and name.

### Example

This statement creates a #painter shader called newPainter:

```python
newPainter = member("3D World").newShader("newPainter", #painter)
```

### See also

*shadowPercentage*

### newTexture

**Usage**

```python
member(whichCastmember).newTexture(newTextureName \ 
  i, #typeIndicator, sourceObjectReference)
```

**Description**

3D command; creates a new texture within the referenced member’s texture palette and returns a reference to the new texture. The only way cast member textures will work is if you specify the cast member in the newTexture constructor.

**Parameters**

- **newTextureName** Required. Specifies the name of the new texture. The name of the new texture must be unique in the referenced cast member’s texture palette.
- **typeIndicator** Optional. Specifies the type of the new texture. If omitted, the new texture is created with no specific type. Valid values include the following:
  - **#fromCastMember** (a cast member)
• #fromImageObject (a Lingo image object)

sourceObjectReference Optional. Specifies a reference to the source cast member or Lingo image object. If omitted, the new texture is created from no specific source. 

sourceObjectReference must refer to a cast member if typeIndicator is #fromCastMember, and it must refer to a Lingo image object if typeIndicator is #fromImageObject.

Example
The first line of this statement creates a new texture called Grass 02 from cast member 5 of castlib 1. The second line creates a blank new texture called Blank.

member("3D World").newTexture("Grass \
02",#fromCastMember,member(5,1))
member("3D World").newTexture("Blank")

normalize

Usage
normalize(vector)
vector.normalize()

Description
3D command; normalizes a vector by dividing the x, y, and z components by the vector’s magnitude. Vectors that have been normalized always have a magnitude of 1.

Parameters
None.

Example
This statement shows the value of the vector MyVec before and after being normalized:

MyVec = vector(-209.9019, 1737.5126, 0.0000)
MyVec.normalize()
-- vector(-0.1199, 0.9928, 0.0000)
put MyVec.magnitude
-- 1.0000

This statement shows the value of the vector ThisVector before and after being normalized.

ThisVector = vector(-50.0000, 0.0000, 0.0000)
normalize(ThisVector)
put ThisVector
-- vector(-1.0000, 0.0000, 0.0000)

See also
getNormalized, randomVector(), magnitude
nothing

Usage
nothing

Description
Command; does nothing. This command is useful for making the logic of an if...then
statement more obvious. A nested if...then...else statement that contains no explicit
command for the else clause may require else nothing, so that Lingo does not interpret the
else clause as part of the preceding if clause.

Parameters
None.

Example
The nested if...then...else statement in this handler uses the nothing command to satisfy
the statement's else clause:

```lingo
-- Lingo syntax
on mouseDown
  if the clickOn = 1 then
    if sprite(1).moveableSprite = TRUE then
      member("Notice").text = "Drag the ball"
    else nothing
  end if
  else member("Notice").text = "Click again"
end if
end
```

```javascript
function mouseDown() {
  if (_mouse.clickOn == 1) {
    if (sprite(1).moveableSprite) {
      member("Notice").text = "Drag the ball";
    } else {
      // do nothing
    }
  } else {
    member("Notice").text = "Click again";
  }
}
```

This handler instructs the movie to do nothing so long as the mouse button is being pressed:

```lingo
-- Lingo syntax
on mouseDown
  repeat while the stillDown
    nothing
  end repeat
end mouseDown
```

```javascript
function mouseDown() {
  do {
    // do nothing
  } while _mouse.stillDown;
}
```

See also
if
nudge()

Usage

-- Lingo syntax
spriteObjRef.nudge(#direction)

// JavaScript syntax
spriteObjRef.nudge(#direction);

Description

QuickTime VR command; nudges the view perspective of the specified QuickTime VR sprite in a specified direction.

Nudging to the right causes the image of the sprite to move to the left. The nudge command has no return value.

Parameters

direction Required. Specifies the direction to nudge the view perspective. Valid values include the following:
• #down
• #downLeft
• #downRight
• #left
• #right
• #up
• #upLeft
• #upRight

Example

This handler causes the perspective of the QTVR sprite to move to the left as long as the mouse button is held down on the sprite:

-- Lingo syntax
on mouseDown me
    repeat while the stillDown
        sprite(1).nudge(#left)
    end repeat
end

// JavaScript syntax
function mouseDown() {
    do {
        sprite(1).nudge(#left);
    } while _mouse.stillDown;
}
**numToChar()**

**Usage**

```
numToChar(integerExpression)
```

**Description**

Function; displays a string containing the single character whose ASCII number is the value of a specified expression. This function is useful for interpreting data from outside sources that are presented as numbers rather than as characters.

ASCII values up to 127 are standard on all computers. Values of 128 or greater refer to different characters on different computers.

**Parameters**

- `integerExpression` Required. Specifies the ASCII number whose corresponding character is returned.

**Example**

This statement displays in the Message window the character whose ASCII number is 65:

```
put numToChar(65)
```

The result is the letter `A`.

This handler removes any nonalphabetic characters from any arbitrary string and returns only capital letters:

```-- Lingo syntax
on ForceUppercase input
    output = EMPTY
    num = length(input)
    repeat with i = 1 to num
        theASCII = charToNum(input.char[i])
        if theASCII = min(max(96, theASCII), 123) then
            theASCII = theASCII - 32
        end if
        if theASCII = min(max(63, theASCII), 91) then
            put numToChar(theASCII) after output
        end if
    end repeat
    return output
end
```

```// JavaScript syntax
function ForceUpperCase(input) {
    output = "";
    num = input.length;
    for (i=1;i<=num;i++) {
        theASCII = input.char[i].charToNum();
        if (theASCII == min(max(96, theASCII), 123) {
            theASCII = theASCII - 32;
        } else if (theASCII == min(max(63, theASCII), 91) {
            output = output + theASCII.numToChar();
        }
    }
    return output;
}
```

**See also**

- `charToNum()`
objectP()

Usage

objectP(expression)

Description

Function; indicates whether a specified expression is an object produced by a parent script, Xtra, or window (TRUE) or not (FALSE).

The P in objectP stands for predicate.

It is good practice to use objectP to determine which items are already in use when you create objects by parent scripts or Xtra instances.

To see an example of objectP() used in a completed movie, see the Read and Write Text movie in the Learning/Lingo folder inside the Director application folder.

Parameters

expression Required. Specifies the expression to test.

Example

This Lingo checks whether the global variable gDataBase has an object assigned to it and, if not, assigns one. This check is commonly used when you perform initializations at the beginning of a movie or section that you don’t want to repeat.

-- Lingo syntax
if objectP(gDataBase) then
  nothing
else
  gDataBase = script("Database Controller").new()
end if

// JavaScript syntax
if (objectP(gDataBase)) {
  // do nothing
} else {
  gDataBase = script("Database Controller").new();
}

See also

floatP(), ilk(), integerP(), stringP(), symbolP()

offset() (string function)

Usage

offset(stringExpression1, stringExpression2)

Description

Function; returns an integer indicating the position of the first character of a string in another string. This function returns 0 if the first string is not found in the second string. Lingo counts spaces as characters in both strings.

On the Macintosh, the string comparison is not sensitive to case or diacritical marks. For example, Lingo considers a and Á to be the same character on the Macintosh.
**Parameters**

*stringExpression1* Required. Specifies the sub-string to search for in *stringExpression2*.

*stringExpression2* Required. Specifies the string that contains the sub-string *stringExpression1*.

**Example**

This statement displays in the Message window the beginning position of the string “media” within the string “Macromedia”:

```plaintext
put offset("media","Macromedia")
```

The result is 6.

This statement displays in the Message window the beginning position of the string “Micro” within the string “Macromedia”:

```plaintext
put offset("Micro","Macromedia")
```

The result is 0, because “Macromedia” doesn’t contain the string “Micro”.

This handler finds all instances of the string represented by *stringToFind* within the string represented by *input* and replaces them with the string represented by *stringToInsert*:

```plaintext
-- Lingo syntax
on SearchAndReplace input, stringToFind, stringToInsert
  output = ""
  findLen = stringToFind.length - 1
  repeat while input contains stringToFind
    currOffset = offset(stringToFind, input)
    output = output & input.char [1..currOffset]
    delete the last char of output
    output = output & stringToInsert
    delete input.char [1.. (currOffset + findLen)]
  end repeat
  set output = output & input
  return output
end

// JavaScript syntax
function SearchAndReplace(input, stringToFind, stringToInsert) {
  output = ""
  findLen = stringToFind.length - 1;
  do {
    currOffset = offset(stringToFind, input);
    output = output + input.char[0..currOffset];
    output = output.toString().substr(0, output.length - 2);
    input = input.substr(currOffset+findLen,input.length);
  } while (input.indexOf(stringToFind) >= 0);
  output = output + input;
  return output;
}
```

**See also**

*chars*, *length*, *contains*, *starts*
offset() (rectangle function)

Usage

```plaintext
rectangle.offset(horizontalChange, verticalChange)
offset (rectangle, horizontalChange, verticalChange)
```

Description

Function; yields a rectangle that is offset from the rectangle specified by `rectangle`.

Parameters

- `horizontalChange` Required. Specifies the horizontal offset, in pixels. When `horizontalChange` is greater than 0, the offset is toward the right of the Stage; when `horizontalChange` is less than 0, the offset is toward the left of the Stage.

- `verticalChange` Required. Specifies the vertical offset, in pixels. When `verticalChange` is greater than 0, the offset is toward the top of the Stage; when `verticalChange` is less than 0, the offset is toward the bottom of the Stage.

Example

This handler moves sprite 1 five pixels to the right and five pixels down:

```plaintext
-- Lingo syntax
on diagonalMove
    newRect = sprite(1).rect.offset(5, 5)
    sprite(1).rect = newRect
end

// JavaScript syntax
function diagonalMove() {
    newRect = sprite(1).rect.offset(5, 5);
    sprite(1).rect = newRect;
}
```

open() (Player)

Usage

```plaintext
_player.open({stringDocPath}, {stringAppPath})
```

// JavaScript syntax

```plaintext
_player.open({stringDocPath}, {stringAppPath});
```

Description

Player method; opens a specified application, and optionally opens a specified file when the application opens.

When either `stringDocPath` or `stringAppPath` are in a different folder than the current movie, you must specify the full pathname to the file or files.

The computer must have enough memory to run both Director and other applications at the same time.

This is a very simple method for opening an application or a document within an application. For more control, look at options available in third-party Xtra extensions.
Parameters

stringDocPath Optional. A string that specifies the document to open when the application specified by stringAppPath opens.

stringAppPath Required. A string that specifies the path to the application to open.

Example

This statement opens the TextEdit application, which is in the folder Applications on the drive HD (Macintosh), and the document named Storyboards:

-- Lingo syntax
_player.open("Storyboards", "HD:Applications:TextEdit")

// JavaScript syntax
_player.open("Storyboards", "HD:Applications:TextEdit");

See also

Player

open() (Window)

Usage

-- Lingo syntax
windowObjRef.open()

// JavaScript syntax
windowObjRef.open();

Description

Window method; opens a window and positions it in front of all other windows.

If no movie is assigned to the window on which open() is called, the Open File dialog box appears.

If the reference to the window object windowObjRef is replaced with a movie's filename, the window uses the filename as the window name. However, a movie must then be assigned to the window by using the window's fileName property.

If the reference to the window object windowObjRef is replaced with a window name, the window takes that name. However, a movie must then be assigned to the window by using the window's fileName property.

To open a window that uses a movie from a URL, use downloadNetThing() to download the movie's file to a local disk first, and then use the file on the disk. This procedure minimizes problems with waiting for the movie to download.

When using a local movie, use preloadMovie() to load at least the first frame of the movie prior to calling open(). This procedure reduces the possibility of movie load delays.

Opening a movie in a window is currently not supported in playback using a browser.

Parameters

None.
Example
This statement opens the window Control Panel and brings it to the front:

-- Lingo syntax
window("Control Panel").open()

// JavaScript syntax
window("Control Panel").open();

See also
close(), downloadNetThing, fileName (Window), preLoadMovie(). Window

openFile()

Usage

-- Lingo syntax
fileioObjRef.openFile(stringFileName, intMode)

// JavaScript syntax
FileioObjRef.openFile(stringFileName, intMode)

Description
Fileio method; Opens a specified file with a specified mode.

Parameters

stringFileName Required. A string that specifies the full path and name of the file to open.

intMode Required. An integer that specifies the mode of the file. Valid values include:

• 0—Read/write
• 1—Read-only
• 2—Writeable

See also
Fileio

openXlib

Usage

openXlib whichFile

Description
Command; opens a specified XLibrary file.

It is good practice to close any file you have opened as soon as you are finished using it. The openXlib command has no effect on an open file.

The openXlib command doesn’t support URLs as file references.

XLibrary files contain Xtra extensions. Unlike openResFile, openXlib makes these Xtra extensions known to Director.

When you open a Scripting Xtra extension using openXlib, you must use closeXlib to close it when Director is finished using it.
In Windows, the .dll extension is optional.

**Note:** This command is not supported in Shockwave Player.

**Parameters**

*whichFile* Required. Specifies the Xlibrary file to open. If the file is not in the folder containing the current movie, *whichFile* must include the pathname.

**Example**

This statement opens the Xlibrary file Video Disc Xlibrary:

```
openXlib "Video Disc Xlibrary"
```

This statement opens the Xlibrary file Xtras, which is in a different folder than the current movie:

```
openXlib "My Drive:New Stuff:Transporter Xtras"
```

**See also**

`closeXlib`, `interface()`

---

### param()

**Usage**

```
param(parameterPosition)
```

**Description**

Function; provides the value of a parameter passed to a handler.

To avoid errors in a handler, this function can be used to determine the type of a particular parameter.

**Parameters**

*parameterPosition* Required. Specifies the parameter's position in the arguments passed to a handler.

**Example**

This handler accepts any number of arguments, adds all the numbers passed in as parameters, and then returns the sum:

---

**Lingo syntax**

```
on AddNumbers
  sum = 0
  repeat with currentParamNum = 1 to the paramCount
    sum = sum + param(currentParamNum)
  end repeat
  return sum
end
```

**JavaScript syntax**

```
function AddNumbers() {
  sum = 0;
  for (currentParamNum=1;currentParamNum<paramCount;currentParamNum++) {
    sum = sum + param(currentParamNum);
  }
  return sum;
}
```
You would use it by passing in the values you wanted to add:

```plaintext
put AddNumbers(3, 4, 5, 6)
-- 18
put AddNumbers(5, 5)
-- 10
```

See also

`getAt`, `param()`, `paramCount()`, `return (keyword)`

### paramCount()

**Usage**

```plaintext
the paramCount
```

**Description**

Function; indicates the number of parameters sent to the current handler.

**Parameters**

None.

**Example**

This statement sets the variable `counter` to the number of parameters that were sent to the current handler:

```plaintext
set counter = the paramCount
```

### parseString()

**Usage**

```plaintext
parserObject.parseString(stringToParse)
```

**Description**

Function; used to parse an XML document that is already fully available to the Director movie. The first parameter is the variable containing the parser object. The return value is `<VOID>` if the operation succeeds, or an error code number string if it fails. Failure is usually due to a problem with the XML syntax or structure. Once the operation is complete, the parser object contains the parsed XML data.

To parse XML at a URL, use `parseURL()`.

**Parameters**

- `stringToParse` Required. Specifies the string of XML data to parse.

**Example**

This statement parses the XML data in the text cast member XMLtext. Once the operation is complete, the variable `gParserObject` will contain the parsed XML data.

```plaintext
errorCode = gParserObject.parseString(member("XMLtext"))
```

See also

`getError() (XML)`, `parseURL()`
parseURL()

Usage

parserObject.parseURL(URLstring {,#handlerToCallOnCompletion} {,objectContainingHandler})

Description

Function; parses an XML document that resides at an external Internet location. The first parameter is the parser object containing an instance of the XML Parser Xtra.

This function returns immediately, so the entire URL may not yet be parsed. It is important to use the doneParsing() function in conjunction with parseURL() to determine when the parsing operation is complete.

Since this operation is asynchronous, meaning it may take some time, you can use optional parameters to call a specific handler when the operation completes.

The return value is void if the operation succeeds, or an error code number string if it fails.

To parse XML locally, use parseString().

Parameters

URLstring Required. Specifies the actual URL at which the XML data resides.

handlerToCallOnCompletion Optional. Specifies the name of the handler that is to be executed once the URL is fully parsed.

objectContainingHandler Optional. Specifies the name of the script object containing the handler handlerToCallOnCompletion. If omitted, the handler is assumed to be a movie handler.

Example

This statement parses the file sample.xml at MyCompany.com. Use doneParsing() to determine when the parsing operation has completed.

errorCode = gParserObject.parseURL("http://www.MyCompany.com/sample.xml")

This Lingo parses the file sample.xml and calls the on parseDone handler. Because no script object is given with the doneParsing() function, the on parseDone handler is assumed to be in a movie script.

errorCode = gParserObject.parseURL("http://www.MyCompany.com/sample.xml", #parseDone)

The movie script contains the on parseDone handler:

on parseDone
    global gParserObject
    if voidP(gParserObject.getError()) then
        put "Successful parse"
    else
        put "Parse error:
            " & gParserObject.getError()
    end if
end
This Lingo parses the document sample.xml at MyCompany.com and calls the on parseDone handler in the script object testObject, which is a child of the parent script TestScript:

```xml
parserObject = new(xtra "XMLParser")
testObject = new(script "TestScript", parserObject)
```

Here is the parent script TestScript:

```xml
property myParserObject

on new me, parserObject
    myParserObject = parserObject
end

on parseDone me
    if voidP(myParserObject.getError()) then
        put "Successful parse"
    else
        put "Parse error:"
        put "   " & myParserObject.getError()
    end if
end
```

See also
- `getError()` (XML), `parseString()`

---

### pass

**Usage**

pass

**Description**

Command; passes an event message to the next location in the message hierarchy and enables execution of more than one handler for a given event.

The `pass` command branches to the next location as soon as the command runs. Any Lingo that follows the `pass` command in the handler does not run.

By default, an event message stops at the first location containing a handler for the event, usually at the sprite level.

If you include the `pass` command in a handler, the event is passed to other objects in the hierarchy even though the handler would otherwise intercept the event.

**Parameters**

None.

**Example**

This handler checks the key presses being entered, and allows them to pass through to the editable text sprite if they are valid characters:

```xml
-- Lingo syntax
on keyDown me
    legalCharacters = "1234567890"
    if legalCharacters contains the key then
        pass
```
else
    beep
end if
end

// JavaScript syntax
function keyDown() {
    legalCharacters = "1234567890";
    if (legalCharacters.indexOf(_key.key) >= 0) {
        pass();
    } else {
        _sound.beep();
    }
}

See also
stopEvent()

pasteClipBoardInto()

Usage

-- Lingo syntax
memberObjRef.pasteClipBoardInto()

// JavaScript syntax
memberObjRef.pasteClipBoardInto();

Description

Member method; pastes the contents of the Clipboard into a specified cast member, and erases
the existing cast member.

Any item that is in a format that Director can use as a cast member can be pasted.

When copying a string from another application, the string's formatting is not retained.

This method provides a convenient way to copy objects from other movies and from other
applications into the Cast window. Because copied cast members must be stored in RAM, avoid
using this command during playback in low memory situations.

When using this method in Shockwave Player, or in the authoring environment and projectors
with the safePlayer property set to TRUE, a warning dialog will allow the user to cancel the
paste operation.

Parameters

None.

Example

This statement pastes the Clipboard contents into the bitmap cast member Shrine:

-- Lingo syntax
member("shrine").pasteClipBoardInto()

// JavaScript syntax
member("shrine").pasteClipBoardInto();

See also

Member, safePlayer
pause() (DVD)

Usage
--- Lingo syntax
dvdObjRef.pause()

// JavaScript syntax
dvdObjRef.pause();

Description
DVD method; pauses playback.

Parameters
None.

See also
DVD

pause() (Sound Channel)

Usage
--- Lingo syntax
soundChannelObjRef.pause()

// JavaScript syntax
soundChannelObjRef.pause();

Description
Sound Channel method; suspends playback of the current sound in a sound channel. A subsequent `play()` method will resume playback.

Parameters
None.

Example
This statement pauses playback of the sound cast member playing in sound channel 1:

--- Lingo syntax
sound(1).pause()

// JavaScript syntax
sound(1).pause();

See also
breakLoop(), play() (Sound Channel), playNext() (Sound Channel), queue(), rewind() (Sound Channel), Sound Channel, stop() (Sound Channel)
pause() (3D)

Usage
member(whichCastmember).model(whichModel).bonesPlayer.pause()
member(whichCastmember).model(whichModel).keyframePlayer.pause()

Description
3D #keyframePlayer and #bonesPlayer modifier command; halts the motion currently being executed by the model. Use the play() command to unpause the motion.

When a model’s motion has been paused by using this command, the model's bonesPlayer.playing property will be set to FALSE.

Parameters
None.

Example
This statement pauses the current animation of the model named Ant3:
member("PicnicScene").model("Ant3").bonesplayer.pause()

See also
play() (3D), playing (3D), playlist

pause() (RealMedia, SWA, Windows Media)

Usage
-- Lingo syntax
memberOrSpriteObjRef.pause()

// JavaScript syntax
memberOrSpriteObjRef.pause();

Description
RealMedia and Windows Media sprite or cast member method; pauses playback of the media stream.
The mediaStatus value becomes #paused.

Calling this method while the RealMedia or Windows Media stream is playing does not change the currentTime property and does not clear the media buffer; this allows subsequent play commands to resume playback without rebuffering the stream.

Parameters
None.
Example

The following examples pause the playing of sprite 2 or the cast member Real.

```
-- Lingo syntax
sprite(2).pause()
member("Real").pause()

// JavaScript syntax
sprite(2).pause();
member("Real").pause();
```

See also

mediaStatus (RealMedia, Windows Media), play() (RealMedia, SWA, Windows Media), seek(), stop() (RealMedia, SWA, Windows Media)

perpendicularTo

Usage

```
vector1.perpendicularTo(vector2)
```

Description

3D vector command; returns a vector perpendicular to both the original vector and a second vector. This command is equivalent to the vector crossProduct command.

Parameters

- `vector2` Required. Specifies the second vector.

Example

In this example, pos1 is a vector on the x axis and pos2 is a vector on the y axis. The value returned by `pos1.perpendicularTo(pos2)` is `vector( 0.0000, 0.0000, 1.00000e4 )`. The last two lines of the example show the vector which is perpendicular to both pos1 and pos2.

```
pos1 = vector(100, 0, 0)
pos2 = vector(0, 100, 0)
put pos1.perpendicularTo(pos2)
-- vector( 0.0000, 0.0000, 1.00000e4 )
```

See also

crossProduct(), cross

pictureP()

Usage

```
-- Lingo syntax
pictureP(pictureValue)

// JavaScript syntax
pictureP(pictureValue);
```

Description

Function; reports whether the state of the picture member property for the specified cast member is TRUE (1) or FALSE (0).

Because pictureP doesn’t directly check whether a picture is associated with a cast member, you must test for a picture by checking the cast member’s picture member property.
Parameters

*pictureValue* Required. Specifies a reference to the picture of a cast member.

Example

The first statement in this example assigns the value of the *picture* member property for the cast member Shrine, which is a bitmap, to the variable *pictureValue*. The second statement checks whether Shrine is a picture by checking the value assigned to *pictureValue*.

--- Lingo syntax

```plaintext
pictureValue = member("Shrine").picture
put pictureP(pictureValue)
```

// JavaScript syntax

```plaintext
var pictureValue = member("Shrine").picture;
put(pictureP(pictureValue))
```

The result is 1, which is the numerical equivalent of `TRUE`.

play() (3D)

Usage

```plaintext
member(whichCastmember).model(whichModel).bonesPlayer.play()
member(whichCastmember).model(whichModel).keyframePlayer.play()
member(whichCastmember).model(whichModel).bonesPlayer.
    play(motionName, looped, startTime, endTime, scale, offset)
member(whichCastmember).model(whichModel).keyframePlayer.
    play(motionName, looped, startTime, endTime, scale, offset)
```

Description

3D *keyframePlayer* and *bonesPlayer* command; initiates or unpause the execution of a motion.

When a model's motion has been initiated or resumed by using this command, the model's *bonesPlayer.playing* property will be set to `TRUE`.

Use *play()* with no parameters to resume the execution of a motion that has been paused with the `pause()` command.

Using the *play()* command to initiate a motion inserts the motion at the beginning of the modifier's playlist. If this interrupts playback of another motion, the interrupted motion remains in the playlist in the next position after the newly initiated motion. When the newly initiated motion ends (if it is non-looping) or if the `playNext()` command is issued, the interrupted motion will resume playback at the point where it was interrupted.

Parameters

*motionName* Required. Specifies the name of the motion to execute. When *motionName* is the only parameter passed to *play()* the motion is executed once by the model from beginning to end at the speed set by the modifier's *playRate* property.

*looped* Optional. Specifies whether the motion plays once (`FALSE`) or continuously (`TRUE`).

*startTime* Optional. Measured in milliseconds from the beginning of the motion. When *looped* is `TRUE`, the first iteration of the loop begins at *offset* and ends at *endTime* with all subsequent repetitions of the motion beginning at *startTime* and end at *endTime*. 
**endTime** Optional. Measured in milliseconds from the beginning of the motion. When `looped` is `FALSE`, the motion begins at `offset` and ends at `endTime`. When `looped` is `TRUE`, the first iteration of the loop begins at `offset` and ends at `endTime` with all subsequent repetitions beginning at `startTime` and end at `endTime`. Set `endTime` to -1 if you want the motion to play to the end.

**playRate** Optional. Specifies the actual speed of the motion’s playback. `playRate` is multiplied by the model’s `#keyframePlayer` or `#bonesPlayer` modifier’s `playRate` property to determine the actual speed of the motion’s playback.

**offset** Optional. Measured in milliseconds from the beginning of the motion. When `looped` is `FALSE`, the motion begins at `offset` and ends at `endTime`. When `looped` is `TRUE`, the first iteration of the loop begins at `offset` and ends at `endTime` with all subsequent repetitions beginning at `startTime` and end at `cropEnd`. You can alternately specify the `offset` parameter with a value of `#synchronized` in order to start the motion at the same relative position in its duration as the currently playing animation is through its own duration.

**Example**

This command causes the model named Walker to begin playback of the motion named Fall. After playing this motion, the model will resume playback of any previously playing motion.

```lingo
sprite(1).member.model("Walker").bonesPlayer.play("Fall", 0, 0, -1, 1, 0)
```

This command causes the model named Walker to begin playback of the motion named Kick. If Walker is currently executing a motion, it is interrupted by Kick and a section of Kick will play in a continuous loop. The first iteration of the loop will begin 2000 milliseconds from the motion’s beginning. All subsequent iterations of the loop will begin 1000 milliseconds from Kick’s beginning and will end 5000 milliseconds from Kick’s beginning. The rate of playback will be three times the `playRate` property of the model’s `bonesPlayer` modifier.

```lingo
sprite(1).member.model("Walker").bonesPlayer.play("Kick", 1, 1000, 5000, 3, 2000)
```

**See also**

`queue()` (3D), `playNext()` (3D), `playRate` (3D), `playlist`, `pause()` (3D), `removeLast()`, `playing` (3D)

**play() (DVD)**

**Usage**

- **Lingo syntax**
  ```lingo
dvdObjRef.play()
dvdObjRef.play(beginTitle, beginChapter, endTitle, endChapter)
dvdObjRef.play(beginTimeList, endTimeList)
  ```

- **JavaScript syntax**
  ```javascript
dvdObjRef.play();
dvdObjRef.play(beginTitle, beginChapter, endTitle, endChapter);
dvdObjRef.play(beginTimeList, endTimeList);
  ```

**Description**

DVD method; starts or resumes playback.
Without parameters, this method resumes playback if paused, or if stopped, starts playback at the top of a disc or at the value specified by the startTimeList property. Playback continues until the value specified by the stopTimeList property, if set.

With the `beginTitle`, `beginChapter`, `endTitle`, and `endChapter` parameters, this method starts playback at a given title and chapter. Playback continues until the specified `endTitle` and `endChapter` parameters, if set.

With the `beginTimeList` and `endTimeList` parameters, this method plays from the value specified by the `beginTimeList` parameter to the value specified by the `endTimeList` parameter.

The following list formats are used for `beginTimeList` and `endTimeList`:

```
[#title:1, #chapter:1, #hours:0, #minutes:1, #seconds:1]
```

or

```
[#title:1, #hours:0, #minutes:1, #seconds:1]
```

This method returns 0 if successful.

**Parameters**

- **beginTitle** Required if starting playback at a given title and chapter. A number that specifies the title that contains the chapter to play. This parameter will override the member’s `startTimeList` property.

- **beginChapter** Required if starting playback at a given title and chapter. A number that specifies the chapter to play. This parameter will override the member’s `startTimeList` property.

- **endTitle** Required if stopping playback at a given title and chapter. A number that specifies the title where playback will stop. This parameter will override the member’s `stopTimeList` property.

- **endChapter** Required if stopping playback at a given title and chapter. A number that specifies the chapter to play. This parameter will override the member’s `stopTimeList` property.

- **beginTimeList** Required if starting playback at a given start time. A property list that specifies the time at which playback starts. This parameter will override the member’s `startTimeList` property.

- **endTimeList** Required if starting playback at a given start time. A property list that specifies the time at which playback stops. This parameter will override the member’s `stopTimeList` property.

**Example**

This statement resumes playback of a paused sprite:

```
-- Lingo syntax
member(12).play()

// JavaScript syntax
member(12).play();
```

These statements start playing at chapter 2 of title 1 and finish playing at chapter 4:

```
member(15).play([#title:1, #chapter:2], [#title:1, #chapter:4])
```

or

```
member(15).play(1,2,1,4)
```
This statement starts playing 10 seconds into chapter 2 and finishes playing at 17 seconds:

member(15).play([#title:2, #seconds:10], [#title:2, #seconds:17])

DVD, startTimeList, stopTimeList

play() (Sound Channel)

Usage

-- Lingo syntax
soundChannelObjRef.play()
soundChannelObjRef.play(memberObjRef)
soundChannelObjRef.play(propList)

// JavaScript syntax
soundChannelObjRef.play();
soundChannelObjRef.play(memberObjRef);
soundChannelObjRef.play(propList);

Description

Sound Channel method; begins playing any sounds queued in a sound channel, or queues and begins playing a given cast member.

Sound cast members take some time to load into RAM before they can begin playback. It's recommended that you queue sounds with queue() before you want to begin playing them and then use the first form of this method. The second two forms do not take advantage of the pre-loading accomplished with the queue() command.

By using an optional property list, you can specify exact playback settings for a sound.

To see an example of play() used in a completed movie, see the Sound Control movie in the Learning/Lingo folder inside the Director application folder.

Parameters

memberObjRef Required if playing a specific cast member. A reference to the cast member object to queue and play.

propList Required if specifying playback settings for a sound. A property list that specifies the exact playback settings for the sound. These properties may be optionally set:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#member</td>
<td>The sound cast member to queue. This property must be provided; all others are optional.</td>
</tr>
<tr>
<td>#startTime</td>
<td>The time within the sound at which playback begins, in milliseconds. The default is the beginning of the sound. See startTime.</td>
</tr>
<tr>
<td>#endTime</td>
<td>The time within the sound at which playback ends, in milliseconds. The default is the end of the sound. See endTime.</td>
</tr>
<tr>
<td>#loopCount</td>
<td>The number of times to play a loop defined with #loopStartTime and #loopEndTime. The default is 1. See loopCount.</td>
</tr>
<tr>
<td>#loopStartTime</td>
<td>The time within the sound to begin a loop, in milliseconds. See loopStartTime.</td>
</tr>
</tbody>
</table>
Example

This statement plays cast member introMusic in sound channel 1:

-- Lingo syntax
sound(1).play(member("introMusic"))

// JavaScript syntax
sound(1).play(member("introMusic"));

The following statement plays cast member creditsMusic in sound channel 2. Playback begins 4 seconds into the sound and ends 15 seconds into the sound. The section from 10.5 seconds to 14 seconds loops 6 times.

-- Lingo syntax
sound(2).play([#member:member("creditsMusic"), #startTime:4000, 
              #endTime:15000, #loopCount:6, #loopStartTime:10500, #loopEndTime:14000])

// JavaScript syntax
sound(2).play(propList("member",member("creditsMusic"), "startTime",4000, 
                  "endTime",15000, "loopCount",6, "loopStartTime",10500, 
                  "loopEndTime",14000));

See also

endTime, loopCount, loopEndTime, loopStartTime, pause() (Sound Channel), preloadTime, queue(). Sound Channel, startTime, stop() (Sound Channel)

play() (RealMedia, SWA, Windows Media)

Usage

-- Lingo syntax
windowsMediaObjRef.play()
realMediaObjRef.play()

// JavaScript syntax
windowsMediaObjRef.play();
realMediaObjRef.play();

Description

Windows Media or RealMedia cast member or sprite method; plays the Windows Media or RealMedia cast member or plays the sprite on the Stage.

For cast members, only audio is rendered if present in the movie. If the cast member is already playing, calling this method has no effect.

Parameters

None.
Example

The following examples start the streaming process for the stream in sprite 2 and the cast member Real.

-- Lingo syntax
sprite(2).play()
member("Real").play()

// JavaScript syntax
sprite(2).play();
member("Real").play();

See also

RealMedia, Windows Media

playFile()

Usage

-- Lingo syntax
soundChannelObjRef.playFile(stringFilePath)

// JavaScript syntax
soundChannelObjRef.playFile(stringFilePath);

Description

Sound Channel method; plays the AIFF, SWA, AU, or WAV sound in a sound channel.

For the sound to be played properly, the correct MIX Xtra must be available to the movie, usually in the Xtras folder of the application.

When the sound file is in a different folder than the movie, stringFilePath must specify the full path to the file.

To play sounds obtained from a URL, it’s usually a good idea to use downloadNetThing() or preloadNetThing() to download the file to a local disk first. This approach can minimize problems that may occur while the file is downloading.

The playFile() method streams files from disk rather than playing them from RAM. As a result, using playFile() when playing digital video or when loading cast members into memory can cause conflicts when the computer tries to read the disk in two places at once.

Parameters

stringFilePath Required. A string that specifies the name of the file to play. When the sound file is in a different folder than the currently playing movie, stringFilePath must also specify the full path to the file.

Example

This statement plays the file named Thunder in channel 1:

-- Lingo syntax
sound(1).playFile("Thunder.wav")

// JavaScript syntax
sound(1).playFile("Thunder.wav");
This statement plays the file named Thunder in channel 3:

-- Lingo syntax
sound(3).playFile(_movie.path & "Thunder.wav")

// JavaScript syntax
sound(3).playFile(_movie.path + "Thunder.wav");

See also
play() (Sound Channel), Sound Channel, stop() (Sound Channel)

**playFromToTime()**

**Usage**

-- Lingo syntax
windowsMediaObjRef.playFromToTime(intStartTime, intEndTime)

// JavaScript syntax
windowsMediaObjRef.playFromToTime(intStartTime, intEndTime);

**Description**

Windows Media sprite method. Starts playback from a specified start time and plays to a specified end time.

**Parameters**

*intStartTime* Required. An integer that specifies the time, in milliseconds, at which playback begins.

*intEndTime* Required. An integer that specifies the time, in milliseconds, at which playback ends.

**Example**

This statement specifies that the sprite named Video should play from the 30 second mark to the 40 second mark.

-- Lingo syntax
sprite("Video").playFromToTime(30000, 40000)

// JavaScript syntax
sprite("Video").playFromToTime(30000, 40000);

See also

Windows Media

**playNext() (Sound Channel)**

**Usage**

-- Lingo syntax
soundChannelObjRef.playNext()

// JavaScript syntax
soundChannelObjRef.playNext();

**Description**

Sound Channel method; immediately interrupts playback of the current sound playing in a sound channel and begins playing the next queued sound.
If no more sounds are queued in the given channel, the sound simply stops playing.

**Parameters**

None.

**Example**

This statement plays the next queued sound in sound channel 2:

```
-- Lingo syntax
sound(2).playNext()

// JavaScript syntax
sound(2).playNext();
```

**See also**

`pause()` (Sound Channel), `play()` (Sound Channel), `Sound Channel.stop()` (Sound Channel)

### playNext() (3D)

**Usage**

```
member(whichMember).model(whichModel).bonesPlayer.playNext()
member(whichMember).model(whichModel).keyframePlayer.playNext()
```

**Description**

3D `#keyframePlayer` and `#bonesPlayer` modifier command; initiates playback of the next motion in the playlist of the model's `#keyframePlayer` or `#bonesPlayer` modifier. The currently playing motion, which is the first entry in the playlist, is interrupted and removed from the playlist.

If motion blending is enabled, and there are two or more motions in the playlist, blending between the current motion and the next one in the playlist will begin when `playNext()` is called.

**Example**

This statement interrupts the motion currently being executed by model 1 and initiates playback of the next motion in the playlist:

```
member("scene").model[1].bonesPlayer.playnext()
```

**See also**

`blend (3D)`, `playlist`

### playerParentalLevel()

**Usage**

```
-- Lingo syntax
dvdObjRef.playerParentalLevel()

// JavaScript syntax
dvdObjRef.playerParentalLevel();
```

**Description**

DVD method; returns the parental level of the player.
Possible parental levels range from 1 to 8.

Parameters

None.

See also

DVD

point()

Usage

-- Lingo syntax
point(intH, intV)

// JavaScript syntax
point(intH, intV);

Description

Top level function and data type. Returns a point that has specified horizontal and vertical coordinates.

A point has both a locH and a locV property.

Point coordinates can be changed by arithmetic operations using Lingo only. For example, the following two points can be added together using Lingo, but NaN is returned using JavaScript syntax:

-- Lingo
pointA = point(10,10)
pointB = point(5,5)
put(pointA + pointB)  
-- point(15,15)

// JavaScript syntax
var pointA = point(10,10);
var pointB = point(5,5);
trace(pointA + pointB);
// NaN

To see an example of point() used in a completed movie, see the Imaging and Vector Shapes movies in the Learning/Lingo folder inside the Director application folder.

Parameters

intH Required. An integer that specifies the horizontal coordinate of the point.

intV Required. An integer that specifies the vertical coordinate of the point.

Example

This statement sets the variable lastLocation to the point (250, 400):

-- Lingo syntax
lastLocation = point(250, 400)

// JavaScript syntax
var lastLocation = point(250, 400);
This statement adds 5 pixels to the horizontal coordinate of the point assigned to the variable myPoint:

```-- Lingo syntax
myPoint.locH = myPoint.locH + 5
```

```// JavaScript syntax
myPoint.locH = myPoint.locH + 5;
```

In Lingo only, the following statements set a sprite’s Stage coordinates to `mouseH` and `mouseV` plus 10 pixels. The two statements are equivalent.

```-- Lingo syntax
sprite(_mouse.clickOn).loc = point(_mouse.mouseH, _mouse.mouseV) + point(10, 10)
sprite(_mouse.clickOn).loc = _mouse.mouseLoc + 10
```

See also

`locH`, `locV`

### pointAt

**Usage**

```member(whichCastmember).model(whichModel).pointAt(
    vectorPosition, vectorUp)
member(whichCastmember).camera(whichCamera).pointAt(
    vectorPosition, vectorUp)
member(whichCastmember).light(whichLight).pointAt(
    vectorPosition, vectorUp)
member(whichCastmember).group(whichGroup).pointAt(
    vectorPosition, vectorUp)
```

**Description**

3D command; rotates the referenced object so that its forward direction vector points at a specified world relative position, then it rotates the referenced object to point it’s up direction vector in the direction hinted at by a specified relative vector.

The object’s front and up direction vectors are defined by the object’s `pointAtOrientation` property.

**Parameters**

- `vectorPosition` Required. Specifies the world relative position. This value can also be a node reference.
- `vectorUp` Optional. Specifies a world relative vector that hints at where the object’s up vector should point. If this parameter isn’t specified, then `pointAt` defaults to using the world’s y axis as the up hinting vector. If you attempt to point the object at a position such that the object’s forward vector is parallel to the world’s y axis, then the world’s x axis is used as the up hinting vector. The direction at which you wish to point the object’s forward direction and the direction specified by `vectorUp` do not need to be perpendicular to each other being as this command only uses the `vectorUp` parameter as a hinting vector.
Example

This example points three objects at the model named Mars: the camera named MarsCam, the light named BrightSpot, and the model named BigGun:

```lingo
thisWorldPosn = member("Scene").model("Mars").worldPosition
member("Scene").camera("MarsCam").pointAt(thisWorldPosn)
member("Scene").light("BrightSpot").pointAt(thisWorldPosn)
member("Scene").model("BigGun").pointAt(thisWorldPosn, \vector(0,0,45))
```

If you use non-uniform scaling and a custom `pointAtOrientation` on the same node, e.g., a model, using `pointAt` will likely cause unexpected non-uniform scaling. This is due to the order in which the non-uniform scaling and the rotation to properly orient the node are applied. To workaround this issue, do one of the following:

- Avoid using non-uniform scaling and non-default `pointAtOrientation` together on the same node.
- Remove your scale prior to using `pointAt`, and then reapply it afterwards.

For example:

```lingo
scale = node.transform.scale
node.scale = vector( 1, 1, 1 )
node.pointAt(vector(0, 0, 0)) -- non-default pointAtOrientation
node.transform.scale = scale
```

See also

`pointAtOrientation`

### `pointInHyperlink()`

**Usage**

```lingo
-- Lingo syntax
spriteObjRef.pointInHyperlink(point)
```

```javascript
// JavaScript syntax
spriteObjRef.pointInHyperlink(point);
```

**Description**

Text sprite function; returns a value (`TRUE` or `FALSE`) that indicates whether the specified point is within a hyperlink in the text sprite. Typically, the point used is the cursor position. This is useful for setting custom cursors.

**Parameters**

- **point** Required. Specifies the point to test.

See also

`cursor()`, `mouseLoc`
pointToChar()

Usage
-- Lingo syntax
spriteObjRef.pointToChar(pointToTranslate)

// JavaScript syntax
spriteObjRef.pointToChar(pointToTranslate);

Description
Function; returns an integer representing the character position located within the text or field sprite at a specified screen coordinate, or returns -1 if the point is not within the text.
This function can be used to determine the character under the cursor.

Parameters

pointToTranslate Required. Specifies the screen coordinate to test.

Example
These statements display the number of the character being clicked, as well as the letter, in the Message window:
--Lingo syntax
property spriteNum

on mouseDown me
   pointClicked = _mouse.mouseLoc
   currentMember = sprite(spriteNum).member
   charNum = sprite(spriteNum).pointToChar(pointClicked)
   actualChar = currentMember.char[charNum]
   put("Clicked character" && charNum & ", the letter" && actualChar)
end

// JavaScript syntax
function mouseDown() {
   var pointClicked = _mouse.mousePosition;
   var currentMember = sprite(this.spriteNum).member;
   var charNum = sprite(this.spriteNum).pointToChar(pointClicked);
   var actualChar = currentMember.getProp("char", charNum);
   put("Clicked character " + charNum + ", the letter " + actualChar);
}

See also
mouseLoc, pointToWord(), pointToItem(), pointToLine(), pointToParagraph()
pointToItem()

Usage

-- Lingo syntax
spriteObjRef.pointToItem(pointToTranslate)

// JavaScript syntax
spriteObjRef.pointToItem(pointToTranslate);

Description

Function; returns an integer representing the item position in the text or field sprite at a specified
screen coordinate, or returns -1 if the point is not within the text. Items are separated by the
itemDelimiter property, which is set to a comma by default.

This function can be used to determine the item under the cursor.

Parameters

pointToTranslate Required. Specifies the screen coordinate to test.

Example

These statements display the number of the item being clicked, as well as the text of the item, in
the Message window:

--Lingo syntax
property spriteNum

on mouseDown me
    pointClicked = _mouse.mouseLoc
    currentMember = sprite(spriteNum).member
    itemNum = sprite(spriteNum).pointToItem(pointClicked)
    itemText = currentMember.item[itemNum]
    put("Clicked item" && itemNum & ", the text" && itemText)
end

// JavaScript syntax
function mouseDown() {
    var pointClicked = _mouse.mouseLoc;
    var currentMember = sprite(this.spriteNum).member;
    var itemNum = sprite(this.spriteNum).pointToItem(pointClicked);
    var itemText = currentMember.getProp("item",itemNum);
    trace( "Clicked item " + itemNum + ", the text " + itemText);
}

See also

itemDelimiter, mouseLoc, pointToChar(), pointToWord(), pointToItem(),
pointToLine(), pointToParagraph()
pointToLine()

Usage
-- Lingo syntax
spriteObjRef.pointToLine(pointToTranslate)

// JavaScript syntax
spriteObjRef.pointToLine(pointToTranslate);

Description
Function; returns an integer representing the line position in the text or field sprite at a specified screen coordinate, or returns -1 if the point is not within the text. Lines are separated by carriage returns in the text or field cast member.
This function can be used to determine the line under the cursor.

Parameters
pointToTranslate Required. Specifies the screen coordinate to test.

Example
These statements display the number of the line being clicked, as well as the text of the line, in the Message window:
-- Lingo syntax
property spriteNum
on mouseDown me
    pointClicked = _mouse.mouseLoc
    currentMember = sprite(spriteNum).member
    lineNum = sprite(spriteNum).pointToLine(pointClicked)
    lineText = currentMember.line[lineNum]
    put("Clicked line" && lineNum & ", the text" && lineText)
end

// JavaScript syntax
function mouseDown() {
    var pointClicked = _mouse.mouseLoc;
    var currentMember = sprite(this.spriteNum).member;
    var lineNum = sprite(this.spriteNum).pointToLine(pointClicked);
    var lineText = currentMember.getProp("line", lineNum);
    put("Clicked line " + lineNum + ", the text " + lineText);
}

See also
ItemDelimiter, mouseLoc, pointToChar(), pointToWord(), pointToItem(), pointToLine(), pointToParagraph()
pointToParagraph()

Usage
-- Lingo syntax
spriteObjRef.pointToParagraph(pointToTranslate)

// JavaScript syntax
spriteObjRef.pointToParagraph(pointToTranslate);

Description
Function; returns an integer representing the paragraph number located within the text or field sprite at a specified at screen coordinate, or returns -1 if the point is not within the text. Paragraphs are separated by carriage returns in a block of text.

This function can be used to determine the paragraph under the cursor.

Parameters
pointToTranslate Required. Specifies the screen coordinate to test.

Example
These statements display the number of the paragraph being clicked, as well as the text of the paragraph, in the message window:

-- Lingo syntax
property spriteNum

on mouseDown me
    pointClicked = _mouse.mouseLoc
    currentMember = sprite(spriteNum).member
    paragraphNum = sprite(spriteNum).pointToParagraph(pointClicked)
    paragraphText = currentMember.paragraph[paragraphNum]
    put("Clicked paragraph" && paragraphNum & ", the text" && paragraphText)
end

// JavaScript syntax
function mouseDown() {
    var pointClicked = _mouse.mouseLoc;
    var currentMember = sprite(this.spriteNum).member;
    var paragraphNum = sprite(this.spriteNum).pointToParagraph(pointClicked);
    var paragraphText = currentMember.getProp("paragraph", paragraphNum);
    trace("Clicked paragraph " + paragraphNum + ", the text " + paragraphText);
}

See also
ItemDelimiter, mouseLoc, pointToChar(), pointToDelete(), pointToItem(),
pointToLine()
**pointToWord()**

**Usage**

-- Lingo syntax
spriteObjRef.pointToWord(pointToTranslate)

// JavaScript syntax
spriteObjRef.pointToWord(pointToTranslate);

**Description**

Function; returns an integer representing the number of a word located within the text or field sprite at a specified screen coordinate, or returns -1 if the point is not within the text. Words are separated by spaces in a block of text.

This function can be used to determine the word under the cursor.

**Parameters**

*pointToTranslate* Required. Specifies the screen coordinate to test.

**Example**

These statements display the number of the word being clicked, as well as the text of the word, in the Message window:

-- Lingo syntax
property spriteNum

on mouseDown me
    pointClicked = _mouse.mouseLoc
    currentMember = sprite(spriteNum).member
    wordNum = sprite(spriteNum).pointToWord(pointClicked)
    wordText = currentMember.word[wordNum]
    put("Clicked word" && wordNum & ", the text" && wordText)
end

// JavaScript syntax
function mouseDown(me) {
    var pointClicked = _mouse.mouseLoc;
    var currentMember = sprite(this.spriteNum).member;
    var wordNum = sprite(this.spriteNum).pointToWord(pointClicked);
    var wordText = currentMember.getProp("word", wordNum);
    trace("Clicked word "+ wordNum + ", the text "+ wordText);
}

**See also**

ItemDelimiter, mouseLoc, pointToChar(), pointToItem(), pointToLine(), pointToParagraph()
**postNetText**

**Usage**

```lingo
postNetText(url, propertyList {,serverOSString} {,serverCharSetString})
postNetText(url, postText {,serverOSString} {,serverCharSetString})
```

**Description**

Command; sends a `POST` request to a URL, which is an HTTP URL, with specified data. This command is similar to `getNetText()`. As with `getNetText()`, the server’s response is returned by `netTextResult(netID)` once `netDone(netID)` becomes 1, and if `netError(netID)` is 0, or okay.

The optional parameters may be omitted without regard to position.

This command also has an additional advantage over `getNetText()`: a `postNetText()` query can be arbitrarily long, whereas the `getNetText()` query is limited to the length of a URL (1K or 4K, depending on the browser).

**Note:** If you use `postNetText` to post data to a domain different from the one the movie is playing from, the movie will display a security alert when playing back in Shockwave Player.

To see an example of `postNetText` used in a completed movie, see the Forms and Post movie in the Learning/Lingo folder inside the Director application folder.

**Parameters**

- **url** Required. Specifies the URL to send the `POST` request to.
- **propertyListOrPostText** Required. Specifies the data to send with the request. When a property list is used instead of a string, the information is sent in the same way a browser posts an HTML form, with `METHOD=POST`. This facilitates the construction and posting of form data within a Director title. Property names correspond to HTML form field names and property values to field values.

  The property list can use either strings or symbols as the property names. If a symbol is used, it is automatically converted to a string when used as the value of a property.

  **Note:** If a program uses the alternate form—a string instead of property list—the string `postText` is sent to the server as an HTTP `POST` request using MIME type "text/plain." This will be convenient for some applications, but is not compatible with HTML forms posting.

- **serverOSString** Optional. Defaults to `UNIX` but may be set to `Windows` or `Mac` and translates any carriage returns in the `postText` argument into those used on the server to avoid confusion. For most applications, this setting is unnecessary because line breaks are usually not used in form responses.

- **serverCharSetString** Optional. Applies only if the user is running on a Shift-JIS (Japanese) system. Its possible settings are "JIS", "EUC", "ASCII", and "AUTO". Posted data is converted from Shift-JIS to the named character set. Returned data is handled exactly as by `getNetText()` (converted from the named character set to Shift-JIS). If you use "AUTO", the posted data from the local character set is not translated; the results sent back by the server are translated as they are for `getNetText()`. "ASCII" is the default if `serverCharSetString` is omitted. "ASCII" provides no translation for posting or results.
Example

This statement omits the `serverCharSetString` parameter:

```lingo
netID = postNetText("www.mydomain.com\database.cgi", "Bill Jones", "Win")
```

This example generates a form from user-entry fields for first and last name, along with a Score. Both `serverOSString` and `serverCharSetString` have been omitted:

```lingo
lastName = member("Last Name").text
firstName = member("First Name").text
totalScore = member("Current Score").text
infoList = ["FName":firstName, "LName":lastName, "Score":totalScore]
netID = postNetText("www.mydomain.com\userbase.cgi", infoList)
```

See also

`getNetText()`, `netTextResult()`, `netDone()`, `netError()`

**power()**

**Usage**

```lingo
power(base, exponent)
```

**Description**

Math function; calculates the value of a specified number to a specified exponent.

**Parameters**

- `base` Required. Specifies the base number.
- `exponent` Required. Specifies the exponent value.

**Example**

This statement sets the variable `vResult` to the value of 4 to the third power:

```lingo
set vResult = power(4,3)
```

**preLoad() (Member)**

**Usage**

```lingo
-- Lingo syntax
memberObjRef.preLoad({toMemberObjRef})
```

```javascript
// JavaScript syntax
memberObjRef.preLoad({toMemberObjRef});
```

**Description**

Member method; preloads a cast member or a range of cast members into memory, and stops preloading when memory is full or when all specified cast members have been preloaded.

When used without the `toMemberObjRef` parameter, `preLoad()` preloads all cast members used from the current frame to the last frame of a movie.

**Parameters**

- `toMemberObjRef` Optional. A reference to the last cast member in a range of cast members that is loaded into memory. The first cast member in the range is specified by `memberObjRef`. 
Example

This statement reports in the Message window whether the QuickTime movie Rotating Chair can be preloaded into memory:

-- Lingo syntax
put(member("Rotating Chair").preload())

// JavaScript syntax
put(member("Rotating Chair").preload());

This `startMovie` handler sets up a Flash movie cast member for streaming and then sets its `bufferSize` property:

-- Lingo syntax
on startMovie
member("Flash Demo").preload = FALSE
member("Flash Demo").bufferSize = 65536
end

// JavaScript syntax
function startMovie(){
    member("Flash Demo").preload = false;
    member("Flash Demo").bufferSize = 65536;
}

Member

preLoad() (Movie)

Usage

-- Lingo syntax
_movie.preLoad({frameNameOrNum})
_movie.preLoad(fromFrameNameOrNum, toFrameNameOrNum)

// JavaScript syntax
_movie.preLoad({frameNameOrNum});
_movie.preLoad(fromFrameNameOrNum, toFrameNameOrNum);

Description

Movie method; preloads cast members in the specified frame or range of frames into memory and stops when memory is full or when all of the specified cast members have been preloaded, as follows:

- When used without arguments, this method preloads all cast members used from the current frame to the last frame of a movie.
- When used with one argument, `frameNameOrNum`, this method preloads all cast members used in the range of frames from the current frame to the frame `frameNameOrNum`, as specified by the frame number or label name.
- When used with two arguments, `fromFrameNameOrNum` and `toFrameNameOrNum`, preloads all cast members used in the range of frames from the frame `fromFrameNameOrNum` to the frame `toFrameNameOrNum`, as specified by the frame number or label name.

The `preLoad()` method also returns the number of the last frame successfully loaded. To obtain this value, use the `result()` method.
Parameters

`frameNameOrNum` Optional. A string that specifies the specific frame to preload, or an integer that specifies the number of the specific frame to preload.

`fromFrameNameOrNum` Required if preloading a range of frames. A string that specifies the name of the label of the first frame in the range of frames to preload, or an integer that specifies the number of the first frame in the range of frames to preload.

`toFrameNameOrNum` Required if preloading a range of frames. A string that specifies the name of the label of the last frame in the range of frames to preload, or an integer that specifies the number of the last frame in the range of frames to preload.

Example

This statement preloads the cast members used from the current frame to the frame that has the next marker:

```-- Lingo syntax
_movie.preLoad(_movie.marker(1))
// JavaScript syntax
_movie.preLoad(_movie.marker(1));```

This statement preloads the cast members used from frame 10 to frame 50:

```-- Lingo syntax
_movie.preLoad(10, 50)
// JavaScript syntax
_movie.preLoad(10, 50);```

See also

`Movie`, `result` preLoadBuffer()

Usage

```-- Lingo syntax
memberObjRef.preLoadBuffer()
// JavaScript syntax
memberObjRef.preLoadBuffer();```

Description

Command; preloads part of a specified Shockwave Audio (SWA) file into memory. The amount preloaded is determined by the `preloadTime` property. This command works only if the SWA cast member is stopped.

When the `preLoadBuffer` command succeeds, the `state` member property equals 2.

Most SWA cast member properties can be tested only after the `preLoadBuffer` command has completed successfully. These properties include: `cuePointNames`, `cuePointTimes`, `currentTime`, `duration`, `percentPlayed`, `percentStreamed`, `bitRate`, `sampleRate`, and `numChannels`.

Parameters

None.
Example

This statement loads the cast member Mel Torme into memory:

-- Lingo syntax
member("Mel Torme").preLoadBuffer()

// JavaScript syntax
member("Mel Torme").preLoadBuffer();

See also

preLoadTime

preLoadMember()

Usage

-- Lingo syntax
_movie.preLoadMember({memberObjRef})
_movie.preLoadMember(fromMemNameOrNum, toMemNameOrNum)

// JavaScript syntax
_movie.preLoadMember({memberObjRef});
_movie.preLoadMember(fromMemNameOrNum, toMemNameOrNum);

Description

Movie method; preloads cast members and stops when memory is full or when all of the specified cast members have been preloaded.

This method returns the cast member number of the last cast member successfully loaded. To obtain this value, use the result() method.

When used without arguments, preLoadMember() preloads all cast members in the movie.

When used with the memberObjRef argument, preLoadMember() preloads just that cast member. If memberObjRef is an integer, only the first cast library is referenced. If memberObjRef is a string, the first member with the string as its name will be used.

When used with the arguments fromMemNameOrNum and toMemNameOrNum, preLoadMember() preloads all cast members in the range specified by the cast member numbers or names.

Parameters

memberObjRef Optional. A reference to the cast member to preload.

fromMemNameOrNum Required when preloading a range of cast members. A string or an integer that specifies the first cast member in the range of cast members to preload.

toMemNameOrNum Required when preloading a range of cast members. A string or an integer that specifies the first cast member in the range of cast members to preload.

See also

Movie, preLoad() (Member), result
preLoadMovie()

Usage

-- Lingo syntax
_movie.preLoadMovie(stringMovieName)

// JavaScript syntax
_movie.preLoadMovie(StringMovieName);

Description

Movie method; preloads the data and cast members associated with the first frame of the specified movie. Preloading a movie helps it start faster when it is started by the go() or play() methods.

To preload cast members from a URL, use preloadNetThing() to load the cast members directly into the cache, or use downloadNetThing() to load a movie on a local disk from which you can load the movie into memory and minimize downloading time.

Parameters

stringMovieName Required. A string that specifies the name of the movie to preload.

Example

This statement preloads the movie Introduction, which is located in the same folder as the current movie:

-- Lingo syntax
_movie.preLoadMovie("Introduction")

// JavaScript syntax
_movie.preLoadMovie("Introduction");

See also
downloadNetThing, go(), Movie, preloadNetThing()

preloadNetThing()

Usage

preloadNetThing (url)

Description

Function; preloads a file from the Internet to the local cache so it can be used later without a download delay. The return value is a network ID that you can use to monitor the progress of the operation.

The preloadNetThing() function downloads the file while the current movie continues playing. Use netDone() to find out whether downloading is finished.

After an item is downloaded, it can be displayed immediately because it is taken from the local cache rather than from the network.

Although many network operations can be active at a time, running more than four concurrent operations usually slows down performance unacceptably.

Neither the cache size nor the Check Documents option in a browser's preferences affects the behavior of the preloadNetThing function.
The `preloadNetThing()` function does not parse a Director file's links. Thus, even if a Director file is linked to casts and graphic files, `preloadNetThing()` downloads only the Director file. You still must preload other linked objects separately.

**Parameters**

`url` Required. Specifies the name of any valid Internet file, such as a Director movie, graphic, or FTP server location.

**Example**

This statement uses `preloadNetThing()` and returns the network ID for the operation:

```plaintext
set mynetid = preloadNetThing("http://www.yourserver.com/menupage/mymovie.dir")
```

After downloading is complete, you can navigate to the movie using the same URL. The movie will be played from the cache instead of the URL, since it's been loaded in the cache.

**See also**

`netDone()`

---

**preMultiply**

**Usage**

`transform1.preMultiply(transform2)`

**Description**

3D transform command; alters a transform by pre-applying the positional, rotational, and scaling effects of another transform.

If `transform2` describes a rotation of 90° about the X axis and `transform1` describes a translation of 100 units in the Y axis, `transform1.multiply(transform2)` will alter this transform so that it describes a translation followed by a rotation. The statement `transform1.preMultiply(transform2)` will alter this transform so that it describes a rotation followed by a translation. The effect is that the order of operations is reversed.

**Parameters**

`transform2` Required. Specifies the transform from which effects are pre-applied to another transform.

**Example**

This statement performs a calculation that applies the transform of the model Mars to the transform of the model Pluto:

```plaintext
member("scene").model("Pluto").transform.preMultiply(
  member("scene").model("Mars").transform)
```
preRotate

Usage

\[\text{transformReference.preRotate}(\text{xAngle}, \text{yAngle}, \text{zAngle})\]
\[\text{transformReference.preRotate}(\text{vector})\]
\[\text{transformReference.preRotate}(\text{positionVector}, \text{directionVector}, \text{angle})\]
\[\text{member(}\text{whichCastmember}).\text{node.transform.preRotate}(\text{xAngle}, \text{yAngle}, \text{zAngle})\]
\[\text{member(}\text{whichCastmember}).\text{node.transform.preRotate}(\text{vector})\]
\[\text{member(}\text{whichCastmember}).\text{node.transform.preRotate}(\text{positionVector}, \text{directionVector}, \text{angle})\]

Description

3D transform command; applies a rotation before the current positional, rotational, and scale offsets held by the referenced transform object. The rotation may be specified as a set of three angles, each of which specify an angle of rotation about the three corresponding axes. These angles may be specified explicitly in the form of \(x\text{Angle}, y\text{Angle},\) and \(z\text{Angle},\) or by a vector, where the \(x\) component of the vector corresponds to the rotation about the \(x\)-axis, the \(y\) about the \(y\)-axis, and the \(z\) about the \(z\)-axis.

Alternatively, the rotation may also be specified as a rotation about an arbitrary axis. This axis is defined in space by \text{positionVector} and \text{directionVector}. The amount of rotation about this axis is specified by \text{angle}.

\text{Node} may be a reference to a model, group, light, or camera.

Parameters

\text{xAngle} Required if applying a rotation using \(x\)-, \(y\)-, and \(z\)-axes. Specifies the angle of rotation around the \(x\)-axis.

\text{yAngle} Required if applying a rotation using \(x\)-, \(y\)-, and \(z\)-axes. Specifies the angle of rotation around the \(y\)-axis.

\text{zAngle} Required if applying a rotation using \(x\)-, \(y\)-, and \(z\)-axes. Specifies the angle of rotation around the \(z\)-axis.

\text{vector} Required if applying a rotation using a vector. Specifies the vector whose angles are used in the rotation.

\text{positionVector} Required if applying a rotation about an arbitrary axis. Specifies the position offset.

\text{directionVector} Required if applying a rotation about an arbitrary axis. Specifies the direction offset.

\text{angle} Required if applying a rotation about an arbitrary axis. Specifies the amount of rotation about an arbitrary axis.

Example

The following statement performs a rotation of 20° about each axis. Since the model’s \text{transform} property is its position, rotation, and scale offsets relative to that model’s parent, and \text{preRotate} applies the change in orientation prior to any existing effects of that model’s \text{transform}, this will rotate the model in place rather than orbiting around its parent.

\[\text{member(}"\text{scene}"\text{).model(}"\text{bip01}"\text{).transform.preRotate(20, 20, 20)}\]
preScale() 469

preScale() is equivalent to:

```lingo
member("scene").model("bip01").rotate(20,20,20).
```

Generally `preRotate()` is only useful when dealing with transform variables. This line will orbit the camera about the point (100, 0, 0) in space, around the y axis, by 180°.

```lingo
t = transform()
t.position = member("scene").camera[1].transform.position
```

```lingo
t.preRotate(vector(100, 0, 0), vector(0, 1, 0), 180)
```

```lingo
member("scene").camera[1].transform = t
```

See also `rotate`

### preScale()

**Usage**

```lingo
transformReference.preScale( xScale, yScale, zScale )
transformReference.preScale( vector )
member( whichCastmember ).node.transform.preScale( xScale, yScale, zScale )
member( whichCastmember ).node.transform.preScale( vector )
```

**Description**

3D transform command; applies a scale prior to the existing positional, rotational, and scaling effects of the given transform.

*Node* may be a reference to a model, group, light, or camera.

**Parameters**

- `xScale` Required if applying a scale using x-, y-, and z-axes. Specifies the scale around the x-axis.
- `yScale` Required if applying a scale using x-, y-, and z-axes. Specifies the scale around the y-axis.
- `zScale` Required if applying a scale using x-, y-, and z-axes. Specifies the scale around the z-axis.
- `vector` Required if applying a scale using a vector. Specifies the vector that contains the scale to apply.

**Example**

**Line 1** of the following Lingo creates a duplicate of Moon1’s transform. Remember that access to a model’s transform property is by reference.

**Line 2** applies a scale to that transform prior to any existing positional or rotational effects of that transform. Assume that the transform represents the positional offset and rotational orbit of Moon1 relative to its parent planet. Lets also assume Moon2’s parent is the same as Moon1’s. If we used `scale()` here instead of `preScale()`, then Moon2 would be pushed out twice as far and rotated about the planet twice as much as is Moon1. This is because the scaling would be applied to the transform’s existing positional and rotational offsets. Using `preScale()` will apply the size change without affecting these existing positional and rotational offsets.

**Line 3** applies an additional 180° rotation about the x-axis of the planet. This will put Moon2 on the opposite side of Moon1’s orbit. Using `preRotate()` would have left Moon2 in the same place as Moon1, spun around its own x-axis by 180°.
**Line 4** assigns this new transform to Moon2.

```plaintext
t = member("scene").model("Moon1").transform.duplicate()
t.preScale(2,2,2)
t.rotate(180,0,0)
member("scene").model("Moon2").transform = t
```

**preTranslate()**

**Usage**

```plaintext
transformReference.preTranslate( xIncrement, yIncrement, \  zIncrement )
transformReference.preTranslate( vector )
member( whichCastmember ).node.transform.preTranslate\( (xIncrement, yIncrement, zIncrement)\)
member( whichCastmember ).node.transform.preTranslate( vector )
```

**Description**

3D transform command; applies a translation before the current positional, rotational, and scale offsets held by the referenced transform object. The translation may be specified as a set of three increments along the three corresponding axes. These increments may be specified explicitly in the form of `xIncrement`, `yIncrement`, and `zIncrement`, or by a vector, where the X component of the vector corresponds to the translation about the X axis, the Y about the Y axis, and the Z about the Z axis.

After a series of transformations are done, in the following order, the model's local origin will be at (0, 0, -100), assuming the model's parent is the world:

```plaintext
model.transform.identity()
model.transform.rotate(0, 90, 0)
model.transform.preTranslate(100, 0, 0)
```

Had `translate()` been used instead of `preTranslate()`, the model's local origin would be at (100, 0, 0) and the model rotated about its own Y axis by 90°. The statement `model.transform.pretranslate(x, y, z)` is equivalent to `model.translate(x, y, z)`. Generally, `preTranslate()` is only useful when dealing with transform variables rather than `model.transform` references.

**Parameters**

- `xIncrement` Required if applying a translation using x-, y-, and z-axes. Specifies the translation around the x-axis.
- `yIncrement` Required if applying a translation using x-, y-, and z-axes. Specifies the translation around the y-axis.
- `zIncrement` Required if applying a translation using x-, y-, and z-axes. Specifies the translation around the z-axis.
- `vector` Required if applying a translation using a vector. Specifies the vector to use in the translation.
Example

```lingo
t = transform()
t.transform.identity()
t.transform.rotate(0, 90, 0)
t.transform.preTranslate(100, 0, 0)
gbModel = member("scene").model("mars")
gbModel.transform = t
put gbModel.transform.position
  -- vector(0.0000, 0.0000, -100.0000)
```

print()

**Usage**

```
-- Lingo syntax
spriteObjRef.print({targetName, #printingBounds})

// JavaScript syntax
spriteObjRef.print({targetName, #printingBounds});
```

**Description**

Command; calls the corresponding `print` ActionScript command, which was introduced in Flash 5. All frames in the Flash movie that have been labeled #p are printed. If no individual frames have been labeled, the whole movie prints.

Because printing of Flash movies is rather complicated, you may benefit from reviewing the section about printing in the Flash 5 documentation before using this sprite function.

**Parameters**

- `targetName` Optional. Specifies the name of the target movie or movie clip to be printed. If omitted (if the target is 0), then the main Flash movie is printed.
- `printingBounds` Optional. Specifies the options for the printing bounds. If omitted, the bounds of the target movie are used. If specified, `printingBounds` must be one of the following values:
  - `#bframe`. If specified, then the printing bounds for each page are changed to match each frame that is being printed.
  - `#bmax`. If specified, then the printing bounds become a large enough virtual rectangle to fit all frames to be printed.

printAsBitmap()

**Usage**

```
-- Lingo syntax
spriteObjRef.printAsBitmap({targetName, #printingBounds})

// JavaScript syntax
spriteObjRef.printAsBitmap({targetName, #printingBounds});
```

**Description**

Flash sprite command; functions much like the `print` command, but works only with Flash sprites. However, `printAsBitmap` can be used to print objects containing alpha channel information.
printFrom()

Usage

-- Lingo syntax
_movie.printFrom(startFrameNameOrNum {, endFrameNameOrNum, redux})

// JavaScript syntax
_movie.printFrom(startFrameNameOrNum {, endFrameNameOrNum, redux});

Description

Movie method; prints whatever is displayed on the Stage in each frame, whether or not the frame is selected, starting at the frame specified by startFrame. Optionally, you can supply endFrame and a reduction (redux) value (100%, 50%, or 25%).

The frame being printed need not be currently displayed. This command always prints at 72 dots per inch (dpi), bitmaps everything on the screen (text will not be as smooth in some cases), prints in portrait (vertical) orientation, and ignores Page Setup settings. For more flexibility when printing from within Director, see PrintOMatic Lite Xtra, which is on the installation disk.

Parameters

startFrameNameOrNum Required. A string or integer that specifies the name or number of the first frame to print.

endFrameNameOrNum Optional. A string or integer that specifies the name or number of the last frame to print.

redux Optional. An integer that specifies the reduction value. Valid values are 100, 50, or 25.

Example

This statement prints what is on the Stage in frame 1:

-- Lingo syntax
_movie.printFrom(1)

// JavaScript syntax
_movie.printFrom(1);

The following statement prints what is on the Stage in every frame from frame 10 to frame 25. The reduction is 50%.

-- Lingo syntax
_movie.printFrom(10, 25, 50)

// JavaScript syntax
_movie.printFrom(10, 25, 50);

See also

Movie
propList()

Usage
-- Lingo syntax
propList()
[:]
propList(string1, value1, string2, value2, ...)
propList(#symbol1, value1, #symbol2, value2, ...)
[#symbol1:value1, #symbol2:value2, ...]

// JavaScript syntax
propList();
propList(string1, value1, string2, value2, ...);

Description
Top level function; creates a property list, where each element in the list consists of a name/value pair.

When creating a property list using the syntax propList() or [:] (Lingo only), with or without parameters, the index of list values begins with 1.

The maximum length of a single line of executable script is 256 characters. Large property lists cannot be created using propList(). To create a property list with a large amount of data, enclose the data in square brackets ([]), put the data into a field, and then assign the field to a variable. The variable's content is a list of the data.

Parameters
string1,string2,... Optional. Strings that specify the name portions of the elements in the list.
value1,value2,... Optional. Values that specify the value portions of the elements in the list.
#symbol1,#symbol2,... (Lingo only) Optional. Symbols that represent the name portions of the elements in the list.

Example
This statement creates a property list with various properties and values, and then displays the various property values in the Message window:

-- Lingo syntax
-- using propList()
colorList = propList(#top,"red", #sides,"blue", #bottom,"green")
-- using brackets
colorList = [#top:"red", #sides:"blue", #bottom:"green"]
put(colorList.top) -- "red"
put(colorList.sides) -- "blue"
put(colorList.bottom) -- "green"

// JavaScript syntax
var colorList = propList("top","red", "sides","blue", "bottom","green");
put(colorList.top) // red
put(colorList.sides) // blue
put(colorList.bottom) // green

See also
list()
proxyServer

Usage
proxyServer serverType, "ipAddress", portNum
proxyServer()

Description
Command; sets the values of an FTP or HTTP proxy server.
Without parameters, proxyServer() returns the settings of an FTP or HTTP proxy server.

Parameters
serverType Optional. A symbol that specifies the type of proxy server. The value can be either #ftp or #http.
ipAddress Optional. A string that specifies the IP address.
portNum Optional. An integer that specifies the port number.

Example
This statement sets up an HTTP proxy server at IP address 197.65.208.157 using port 5:
proxyServer #http,"197.65.208.157",5
This statement returns the port number of an HTTP proxy server:
put proxyServer(#http,#port)
If no server type is specified, the function returns 1.
This statement returns the IP address string of an HTTP proxy server:
put proxyServer(#http)
This statement turns off an FTP proxy server:
proxyServer #ftp,#stop

ptToHotSpotID()

Usage
-- Lingo syntax
spriteObjRef.ptToHotSpotID(point)

// JavaScript syntax
spriteObjRef.ptToHotSpotID(point);

Description
QuickTime VR function; returns the ID of the hotspot, if any, that is at the specified point. If there is no hotspot, the function returns 0.

Parameters
point Required. Specifies the point to test.
puppetPalette()

Usage

-- Lingo syntax
_movie.puppetPalette(palette {, speed} {, frames})

// JavaScript syntax
_movie.puppetPalette(palette {, speed} {, frames});

Description

Movie method; causes the palette channel to act as a puppet and lets script override the palette setting in the palette channel of the Score and assign palettes to the movie.

The puppetPalette() method sets the current palette to the palette cast member specified by palette. If palette evaluates to a string, it specifies the cast library name of the palette. If palette evaluates to an integer, it specifies the member number of the palette.

For best results, use the puppetPalette() method before navigating to the frame on which the effect will occur so that Director can map to the desired palette before drawing the next frame.

You can fade in the palette by replacing speed with an integer from 1 (slowest) to 60 (fastest). You can also fade in the palette over several frames by replacing frames with an integer for the number of frames.

A puppet palette remains in effect until you turn it off using the syntax _movie.puppetPalette(0). No subsequent palette changes in the Score are obeyed when the puppet palette is in effect.

Note: The browser controls the palette for the entire Web page. Thus, Shockwave Player always uses the browser’s palette.

Parameters

- palette Required. A string or integer that specifies the name or number of the new palette.
- speed Optional. An integer that specifies the speed of a fade. Valid values range from 1 to 60.
- frames Optional. An integer that specifies the number of frames over which a fade takes place.

Example

This statement makes Rainbow the movie's palette:

-- Lingo syntax
_movie.puppetPalette("Rainbow")

// JavaScript syntax
_movie.puppetPalette("Rainbow");

The following statement makes Grayscale the movie's palette. The transition to the Grayscale palette occurs over a time setting of 15, and over 20 frames.

-- Lingo syntax
_movie.puppetPalette("Rainbow", 15, 20)

// JavaScript syntax
_movie.puppetPalette("Rainbow", 15, 20);

See also

Movie
puppetSprite()

Usage

-- Lingo syntax
_movie.puppetSprite(intSpriteNum, bool)

// JavaScript syntax
_movie.puppetSprite(intSpriteNum, bool);

Description

Movie method; determines whether a sprite channel is a puppet and under script control (TRUE) or not a puppet and under the control of the Score (FALSE).

While the playhead is in the same sprite, turning off the sprite channel's puppetting using the syntax _movie.puppetSprite(intSpriteNum, FALSE) resets the sprite's properties to those in the Score.

The sprite channel's initial properties are whatever the channel's settings are when the puppetSprite() method is executed. You can use script to change sprite properties as follows:

• If a sprite channel is a puppet, any changes that script makes to the channel's sprite properties remain in effect after the playhead exits the sprite.

• If a sprite channel is not a puppet, any changes that script makes to a sprite last for the life of the current sprite only.

The channel must contain a sprite when you use the puppetSprite() method.

Making the sprite channel a puppet lets you control many sprite properties—such as member, locH, and width—from script after the playhead exits the sprite.

Use the syntax _movie.puppetSprite(intSpriteNum, FALSE) to return control to the Score when you finish controlling a sprite channel from script and to avoid unpredictable results that may occur when the playhead is in frames that aren't intended to be puppets.

Note: Version 6 of Director introduced autopuppetting, which made it unnecessary to explicitly puppet a sprite under most circumstances. Explicit control is still useful if you want to retain complete control over a channel's contents even after a sprite span has finished playing.

Parameters

intSpriteNum Required. An integer that specifies the sprite channel to test.

bool Required. A boolean value that specifies whether a sprite channel is under script control (TRUE) or under the control of the Score (FALSE).

Example

This statement makes the sprite in channel 15 a puppet:

-- Lingo syntax
_movie.puppetSprite(15, TRUE)

// JavaScript syntax
_movie.puppetSprite(15, true);
This statement removes the puppet condition from the sprite in the channel numbered \( i + 1 \):

```lua
-- Lingo syntax
_movie.puppetSprite(i + 1, FALSE)

// JavaScript syntax
_movie.puppetSprite(i + 1, false);
```

See also

`makeScriptedSprite()`, `Movie`, `Sprite Channel`

**puppetTempo()**

**Usage**

```lua
-- Lingo syntax
_movie.puppetTempo(intTempo)

// JavaScript syntax
_movie.puppetTempo(intTempo);
```

**Description**

Movie method; causes the tempo channel to act as a puppet and sets the tempo to a specified number of frames.

When the tempo channel is a puppet, script can override the tempo setting in the Score and change the tempo assigned to the movie.

It's unnecessary to turn off the puppet tempo condition to make subsequent tempo changes in the Score take effect.

**Note:** Although it is theoretically possible to achieve frame rates up to 30,000 frames per second (fps) with the `puppetTempo()` method, you could do this only with little animation and a very powerful machine.

**Parameters**

`intTempo` Required. An integer that specifies the tempo.

**Example**

This statement sets the movie's tempo to 30 fps:

```lua
-- Lingo syntax
_movie.puppetTempo(30)

// JavaScript syntax
_movie.puppetTempo(30);
```

This statement increases the movie's old tempo by 10 fps:

```lua
-- Lingo syntax
_movie.puppetTempo(oldTempo + 10)

// JavaScript syntax
_movie.puppetTempo(oldTempo + 10);
```

See also

`Movie`
puppetTransition()

Usage

-- Lingo syntax
_movie.puppetTransition(memberObjRef)
_movie.puppetTransition(int {, time} {, size} {, area})

// JavaScript syntax
_movie.puppetTransition(memberObjRef);
_movie.puppetTransition(int {, time} {, size} {, area});

Description

Movie method; performs the specified transition between the current frame and the next frame.

To use an Xtra transition cast member, use the puppetTransition(memberObjRef) syntax.

To use a built-in Director transition, replace int with a value in the following table. Replace time with the number of quarter seconds used to complete the transition. The minimum value is 0; the maximum is 120 (30 seconds). Replace size with the number of pixels in each chunk of the transition. The minimum value is 1; the maximum is 128. Smaller chunk sizes yield smoother transitions but are slower.

</tbody>
</table>
Transitions marked with an asterisk (*) do not work on monitors set to 32 bits.

There is no direct relationship between a low time value and a fast transition. The actual speed of the transition depends on the relation of size and time. For example, if size is 1 pixel, the transition takes longer no matter how low the time value, because the computer has to do a lot of work. To make transitions occur faster, use a larger chunk size, not a shorter time.

Replace area with a value that determines whether the transition occurs only in the changing area (TRUE) or over the entire Stage (FALSE, default). The area variable is an area within which sprites have changed.

Parameters

- **memberObjRef** Required if using an Xtra transition cast member. A reference to the Xtra cast member to use as the transition.
- **int** Required if using a built-in Director transition. An integer that specifies the number of the transition to use.
- **time** Optional. An integer that specifies that number of quarter seconds used to complete the transition. Valid values range from 0 to 120.
- **size** Optional. An integer that specifies the number of pixels in each chunk of the transition. Valid values range from 1 to 128.
- **area** Optional. A boolean value that specifies whether the transition occurs only in the changing area (TRUE) or over the entire Stage (FALSE).

Example

The following statement performs a wipe right transition. Because no value is specified for area, the transition occurs over the entire Stage, which is the default.

```lingo
_movie.puppetTransition(1)
```

```
// JavaScript syntax
_movie.puppetTransition(1);
```
This statement performs a wipe left transition that lasts 1 second, has a chunk size of 20, and occurs over the entire Stage:

-- Lingo syntax
_movie.puppetTransition(2, 4, 20, FALSE)

// JavaScript syntax
_movie.puppetTransition(2, 4, 20, false);

See also
Movie

put()

Usage

-- Lingo syntax
put(value)

// JavaScript syntax
put(value);

Description

Top level function; evaluates an expression and displays the result in the Message window.

The functionality of this method is identical to the top level trace() method, which is available to both Lingo and JavaScript syntax.

This method can be used as a debugging tool by tracking the values of variables as a movie plays.

Parameters

value Required. The expression to evaluate.

Example

This statement displays the time in the Message window:

-- Lingo syntax
put(_system.time())

// JavaScript syntax
put(_system.time());

This statement displays the value assigned to the variable bid in the Message window:

-- Lingo syntax
bid = "Johnson"
put(bid) -- "Johnson"

// JavaScript syntax
var bid = "Johnson";
put(bid); // Johnson

See also

trace()
qtRegisterAccessKey()

Usage

-- Lingo syntax
qtRegisterAccessKey(categoryString, keyString)

// JavaScript syntax
qtRegisterAccessKey(categoryString, keyString);

Description

Command; allows registration of a key for encrypted QuickTime media.

The key is an application-level key, not a system-level key. After the application unregisters the key or shuts down, the media will no longer be accessible.

Note: For security reasons, there is no way to display a listing of all registered keys.

See also

qtUnRegisterAccessKey()

qtUnRegisterAccessKey()

Usage

-- Lingo syntax
qtUnRegisterAccessKey(categoryString, keyString)

// JavaScript syntax
qtUnRegisterAccessKey(categoryString, keyString);

Description

Command; allows the key for encrypted QuickTime media to be unregistered.

The key is an application-level key, not a system-level key. After the application unregisters the key, only movies encrypted with this key continue to play. Other media will no longer be accessible.

See also

qtRegisterAccessKey()

queue()

Usage

-- Lingo syntax
soundChannelObjRef.queue(memberObjRef)
soundChannelObjRef.queue(propList)

// JavaScript syntax
soundChannelObjRef.queue(memberObjRef);
soundChannelObjRef.queue(propList);

Description

Sound Channel method; adds a sound cast member to the queue of a sound channel.
Once a sound has been queued, it can be played immediately with the `play()` method. This is because Director preloads a certain amount of each sound that is queued, preventing any delay between the `play()` method and the start of playback. The default amount of sound that is preloaded is 1500 milliseconds. This parameter can be modified by passing a property list containing one or more parameters with the `queue()` method. These parameters can also be passed with the `setPlayList()` method.

To see an example of `queue()` used in a completed movie, see the Sound Control movie in the Learning/Lingo folder inside the Director application folder.

**Parameters**

- `memberObjRef` Required if specifying a sound cast member. A reference to the sound cast member to queue.
- `propList` Required if passing a property list as parameters. A property list that applies to the sound cast member to queue. These properties include:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>#member</code></td>
<td>The sound cast member to queue. This property must be provided; all others are optional.</td>
</tr>
<tr>
<td><code>#startTime</code></td>
<td>The time within the sound at which playback begins, in milliseconds. The default is the beginning of the sound. See <code>startTime</code>.</td>
</tr>
<tr>
<td><code>#endTime</code></td>
<td>The time within the sound at which playback ends, in milliseconds. The default is the end of the sound. See <code>endTime</code>.</td>
</tr>
<tr>
<td><code>#loopCount</code></td>
<td>The number of times to play a loop defined with <code>#loopStartTime</code> and <code>#loopEndTime</code>. The default is 1. See <code>loopCount</code>.</td>
</tr>
<tr>
<td><code>#loopStartTime</code></td>
<td>The time within the sound to begin a loop, in milliseconds. See <code>loopStartTime</code>.</td>
</tr>
<tr>
<td><code>#loopEndTime</code></td>
<td>The time within the sound to end a loop, in milliseconds. See <code>loopEndTime</code>.</td>
</tr>
<tr>
<td><code>#preloadTime</code></td>
<td>The amount of the sound to buffer before playback, in milliseconds. See <code>preloadTime</code>.</td>
</tr>
</tbody>
</table>

**Example**

The following handler queues and plays two sounds. The first sound, cast member Chimes, is played in its entirety. The second sound, cast member introMusic, is played starting at its 3-second point, with a loop repeated 5 times from the 8-second point to the 8.9 second point, and stopping at the 10-second point.

```lingo
-- Lingo syntax
on playMusic
    sound(2).queue(member("Chimes"))
    sound(2).queue([#member:member("introMusic"), #startTime:3000, "endTime":10000, #loopCount:5, #loopStartTime:8000, #loopEndTime:8900])
    sound(2).play()
end playMusic
```

```javascript
// JavaScript syntax
function playMusic() {
    sound(2).queue(member("Chimes"))
    sound(2).queue(propList("member",member("introMusic"), "startTime",3000, "endTime",10000, "loopCount",5, "loopStartTime",8000, "loopEndTime",8900))
    sound(2).play();
}
```
queue() (3D)

Usage

member(whichCastmember).model(whichModel).bonesPlayer.queue(
  motionName {, looped, startTime, endTime, scale, offset})
member(whichCastmember).model(whichModel).keyframePlayer.queue(motionName {, looped, startTime, endTime, scale, offset})

Description

3D keyframePlayer and bonesPlayer modifier command; adds a specified motion to the end of the modifier's playlist property. The motion is executed by the model when all the motions ahead of it in the playlist are finished playing.

Parameters

- **motionName** Required. Specifies the name of the motion to add.
- **looped** Optional. Specifies whether the motion plays once (FALSE) or continuously (TRUE).
- **startTime** Optional. Measured in milliseconds from the beginning of the motion. When looped is FALSE, the motion begins at offset and ends at endTime. When looped is TRUE, the first iteration of the loop begins at offset and ends at endTime. All subsequent repetitions begin at startTime and end at endTime.
- **endTime** Optional. Measured in milliseconds from the beginning of the motion. When looped is FALSE, the motion begins at offset and ends at endTime. When looped is TRUE, the first iteration of the loop begins at offset and ends at endTime. All subsequent repetitions begin at cropStart and end at endTime. Set endTime to -1 if you want the motion to play to the end.
- **scale** Optional. Specifies the actual speed of the motion's playback. scale is multiplied by the playRate property of the model's #keyframePlayer modifier or #bonesPlayer modifier to determine the actual speed of the motion's playback.
- **offset** Optional. Measured in milliseconds from the beginning of the motion. When looped is FALSE, the motion begins at offset and ends at endTime. When looped is TRUE, the first iteration of the loop begins at offset and ends at endTime. All subsequent repetitions begin at startTime and end at endTime.

Example

The following Lingo adds the motion named Fall to the end of the bonesPlayer playlist of the model named Walker. When all motions before Fall in the playlist have been executed, Fall will play one time from beginning to end.

```lingo
sprite(1).member.model("Walker").bonesPlayer.queue("Fall", 0, 0, -1, 1, 0)
```
The following Lingo adds the motion named Kick to the end of the bonesPlayer playlist of the model named Walker. When all motions before Kick in the playlist have been executed, a section of Kick will play in a continuous loop. The first iteration of the loop will begin 2000 milliseconds from the motion's beginning. All subsequent iterations of the loop will begin 1000 milliseconds from Kick's beginning and will end 5000 milliseconds from Kick's beginning. The rate of playback will be three times the playRate property of the model's bonesPlayer modifier.

```
sprite(1).member.model("Walker").bonesPlayer.queue("Kick", 1, \
1000, 5000, 3, 2000)
```

`play()` (3D), `playNext()` (3D), `playRate` (3D)

### quickTimeVersion()

**Usage**

```
-- Lingo syntax
quickTimeVersion()

// JavaScript syntax
quickTimeVersion();
```

**Description**

Function; returns a floating-point value that identifies the current installed version of QuickTime and replaces the current `QuickTimePresent` function.

In Windows, if multiple versions of QuickTime 3.0 or later are installed, `quickTimeVersion()` returns the latest version number. If a version before QuickTime 3.0 is installed, `quickTimeVersion()` returns version number 2.1.2 regardless of the version installed.

**Parameters**

None.

**Example**

This statement uses `quickTimeVersion()` to display in the Message window the version of QuickTime that is currently installed:

```
-- Lingo syntax
put(quickTimeVersion())

// JavaScript syntax
put(quickTimeVersion());
```

### quit()

**Usage**

```
-- Lingo syntax
_player.quit()

// JavaScript syntax
_player.quit();
```

**Description**

Player method; exits from Director or a projector to the Windows desktop or Macintosh Finder.
Parameters
None.

Example
This statement tells the computer to exit to the Windows desktop or Macintosh Finder when the user presses Control+Q in Windows or Command+Q on the Macintosh:

-- Lingo syntax
if (_key.key = "q" and _key.commandDown) then
  _player.quit()
end if

// JavaScript syntax
if (_key.key == "q" && _key.commandDown) {
  _player.quit();
}

See also
Player

ramNeeded()

Usage
-- Lingo syntax
_movie.ramNeeded(intFromFrame, intToFrame)

// JavaScript syntax
_movie.ramNeeded(intFromFrame, intToFrame):

Description
Movie method; determines the memory needed, in bytes, to display a range of frames. For example, you can test the size of frames containing 32-bit artwork: if `ramNeeded()` is larger than `freeBytes()`, then go to frames containing 8-bit artwork and divide by 1024 to convert bytes to kilobytes (K).

Parameters

  `intFromFrame` Required. An integer that specifies the number of the first frame in the range.

  `intToFrame` Required. An integer that specifies the number of the last frame in the range.

Example
This statement sets the variable `frameSize` to the number of bytes needed to display frames 100 to 125 of the movie:

-- Lingo syntax
frameSize = _movie.ramNeeded(100, 125)

// JavaScript syntax
var frameSize = _movie.ramNeeded(100, 125);
This statement determines whether the memory needed to display frames 100 to 125 is more than the available memory, and, if it is, branches to the section using cast members that have lower color depth:

-- Lingo syntax
if (_movie.ramNeeded(100, 125) > _system.freeBytes) then
    _movie.go("8-bit")
end if

// JavaScript syntax
if (_movie.ramNeeded(100, 125) > _system.freeBytes) {
    _movie.go("8-bit");
}

See also
freeBytes(), Movie

random()

Usage

-- Lingo syntax
random(integerExpression)

// JavaScript syntax
random(integerExpression);

Description

Top level function; returns a random integer in the range 1 to a specified value. This function can be used to vary values in a movie, such as to vary the path through a game, assign random numbers, or change the color or position of sprites.

To start a set of possible random numbers with a number other than 1, subtract the appropriate amount from the random() function. For example, the expression random(n + 1) - 1 uses a range from 0 to the number n.

Parameters

integerExpression Required. Specifies the maximum value of the random number.

Example

This statement assigns random values to the variable diceRoll:

-- Lingo syntax
diceRoll = (random(6) + random(6))

// JavaScript syntax
var diceRoll = (random(6) + random(6));

This statement randomly changes the foreground color of sprite 10:

-- Lingo syntax
sprite(10).foreColor = (random(256) - 1)

// JavaScript syntax
sprite(10).foreColor = (random(256) - 1);
This handler randomly chooses which of two movie segments to play:

```plaintext
-- Lingo syntax
on SelectScene
    if (random(2) = 2) then
        _movie.go("11a")
    else
        _movie.go("11b")
    end if
end

// JavaScript syntax
function SelectScene() {
    if (random(2) == 1) {
        _movie.go("11a");
    } else {
        _movie.go("11b");
    }
}
```

This statement produces a random multiple of 5 in the range 5 to 100:

```plaintext
-- Lingo syntax
theScore = (5 * random(20))

// JavaScript syntax
var theScore = (5 * random(20));
```

### randomVector()

**Usage**

```plaintext
-- Lingo syntax
randomVector()

// JavaScript syntax
randomVector();
```

**Description**

Top level function; returns a unit vector describing a randomly chosen point on the surface of a unit sphere.

This function differs from `vector(random(10)/10.0, random(10)/10.0, random(10)/10.0)` in that the resulting vector using `randomVector()` is guaranteed to be a unit vector.

A unit vector always has a length of one.

**Parameters**

None.
Example
These statements create and display two randomly defined unit vectors in the Message window:

```lingo
-- Lingo syntax
vec1 = randomVector()
vec2 = randomVector()
put(vec1 & RETURN & vec2)
```

```javascript
// JavaScript syntax
var vec1 = randomVector();
var vec2 = randomVector();
put(vec1 + "\n" + vec2);
```

See also
`vector()`

randomVector

Usage
`randomVector()`

Description
3D command; returns a unit vector describing a randomly chosen point on the surface of a unit sphere. This method differs from `vector( random(10)/10.0, random(10)/10.0, random(10)/10.0)`, in that the resulting vector is guaranteed to be a unit vector.

Parameters
None.

Example
These statements create and display two randomly defined unit vectors in the Message window:

```lingo
vec = randomVector()
put vec
-- vector(-0.1155, 0.9833, -0.1408)
vec2 = randomVector()
put vec2
-- vector(0.0042, 0.8767, 0.4810)
```

See also
`getNormalized`, `generateNormals()`, `normalize`

rawNew()

Usage
`parentScript.rawNew()`

rawNew(parentScript)

Description
Function; creates a child object from a parent script without calling its `on new` handler. This allows a movie to create child objects without initializing the properties of those child objects. This is particularly useful when you want to create large numbers of child objects for later use. To initialize the properties of one of these raw child objects, call its `on new` handler.
Parameters

None.

Example

This statement creates a child object called RedCar from the parent script CarParentScript without initializing its properties:

RedCar = script("CarParentScript").rawNew()

This statement initializes the properties of the child object RedCar:

RedCar.new()

See also

new(), script()

readChar()

Usage

-- Lingo syntax
fileioObjRef.readChar()

// JavaScript syntax
fileioObjRef.readChar();

Description

Fileio method; Reads the next character of a file and returns it as an ASCII code value.

You must first open a file by calling openFile() before using readChar() to read a character.

Parameters

None.

See also

Fileio, openFile()

readFile()

Usage

-- Lingo syntax
fileioObjRef.readFile()

// JavaScript syntax
fileioObjRef.readFile();

Description

Fileio method; Reads from the current position to the end of a specified file, and returns the result as a string.

You must first open a file by calling openFile() before using readFile() to read a file.

Parameters

None.
See also
Fileio, openFile()

readLine()

Usage
-- Lingo syntax
fileioObjRef.readLine()

// JavaScript syntax
fileioObjRef.readLine();

Description
Fileio method; Reads the next line of a file, including the next RETURN, and returns it as a string.
You must first open a file by calling openFile() before using readLine() to read a line.

Parameters
None.

See also
Fileio, openFile()

readToken()

Usage
-- Lingo syntax
fileioObjRef.readToken(stringSkip, stringBreak)

// JavaScript syntax
fileioObjRef.readToken(stringSkip, stringBreak);

Description
Fileio method; Reads the next token and returns it as a string.
You must first open a file by calling openFile() before using readToken() to read a token.

Parameters
stringSkip Required. A string that specifies the set of characters after which the token starts.
The string stringSkip is not included in the returned string.

stringBreak Required. A string that specifies the set of characters before which the token ends.
The string stringBreak is not included in the returned string.

See also
Fileio, openFile()
readWord()

Usage
-- Lingo syntax
fileioObjRef.readWord()

// JavaScript syntax
fileioObjRef.readWord();

Description
Fileio method; Reads the next word of a file and returns it as a string.

You must first open a file by calling openFile() before using readWord() to read a word.

Parameters
None.

See also
Fileio, openFile()

realPlayerNativeAudio()

Usage
-- Lingo syntax
realPlayerNativeAudio()

// JavaScript syntax
realPlayerNativeAudio();

Description
RealMedia function; allows you to get or set the global flag that determines whether the audio
portion of the RealMedia cast member is processed by RealPlayer (TRUE) or by Director (FALSE).
This function returns the previous value of the flag.

To be effective, this flag must be set before RealPlayer is first loaded (when the first RealMedia
cast member is encountered in the Score or with the first Lingo reference to a RealMedia cast
member); any changes to this flag after RealPlayer is loaded are ignored. This flag should be
executed in a prepareMovie event handler in a movie script. This flag is set for the entire session
(from the time the Shockwave Player is launched until it is closed and relaunched), not just for
the duration of the current movie.

By default, this flag is set to FALSE and audio is processed by Director, which allows you to set the
soundChannel property and use the standard Lingo sound methods and properties to manipulate
the audio stream of a RealMedia sprite, including mixing RealAudio with other Director audio. If
this flag is set to TRUE, Lingo control of the sound channel is not processed, and the sound is
handled by RealPlayer.

Parameters
None.
Example

The following code shows that the `realPlayerNativeAudio()` function is set to `FALSE`, which means that audio in the RealMedia cast member will be processed by Director:

```-- Lingo syntax
put(realPlayerNativeAudio())
-- 0
```

```// JavaScript syntax
trace(realPlayerNativeAudio()); // 0
```

The following code sets the `realPlayerNativeAudio()` function to `TRUE`, which means that audio in the RealMedia stream will be processed by RealPlayer and all Lingo control of the sound channel will be ignored:

```-- Lingo syntax
realPlayerNativeAudio(TRUE)
```

```// JavaScript syntax
realPlayerNativeAudio(1);
```

See also

`soundChannel (RealMedia)`

`realPlayerPromptToInstall()`

Usage

```-- Lingo syntax
realPlayerPromptToInstall()
```

```// JavaScript syntax
realPlayerPromptToInstall();
```

Description

RealMedia function; allows you to get or set a global flag that determines whether automatic detection and alert for RealPlayer 8 is enabled (`TRUE`) or not (`FALSE`).

By default, this function is set to `TRUE`, which means that if users do not have RealPlayer 8 and attempt to load a movie containing RealMedia, they are automatically asked if they want to go to the RealNetworks website and install RealPlayer. You can set this flag to `FALSE` if you want to create your own detection and alert system using the `realPlayerVersion()` function on page 493 and custom code. If this flag is set to `FALSE` and an alternate RealPlayer 8 detection and alert system is not in place, users without RealPlayer will be able to load movies containing RealMedia cast members, but the RealMedia sprites will not appear.

This function detects the build number of the RealPlayer installed on the user’s system to determine whether RealPlayer 8 is installed. On Windows systems, build numbers 6.0.8.132 or later indicate that RealPlayer 8 is installed. On Macintosh systems, RealPlayer Core component build numbers 6.0.7.1001 or later indicate that RealPlayer 8 is installed.

This flag should be executed in a `prepareMovie` event handler in a movie script.

This function returns the previous value of the flag.
Parameters

None.

Example

The following code shows that the `realPlayerPromptToInstall()` function is set to `TRUE`, which means users who do not have RealPlayer will be prompted to install it:

```-- Lingo syntax
put(realPlayerPromptToInstall()) -- 1

// JavaScript syntax
-- Lingo syntax
trace(realPlayerPromptToInstall()); // 1```

The following code sets the `realPlayerPromptToInstall()` function to `FALSE`, which means that users will not be prompted to install RealPlayer unless you have created a detection and alert system:

```-- Lingo syntax
realPlayerPromptToInstall(FALSE)

// JavaScript syntax
realPlayerPromptToInstall(0);```

`realPlayerVersion()`

Usage

```-- Lingo syntax
realPlayerVersion()

// JavaScript syntax
realPlayerVersion();```

Description

RealMedia function; returns a string identifying the build number of the RealPlayer software installed on the user's system, or an empty string if RealPlayer is not installed. Users must have RealPlayer 8 or later in order to view Director movies containing RealMedia content. On Windows systems, build numbers 6.0.8.132 or later indicate that RealPlayer 8 is installed. On Macintosh systems, RealPlayer Core component build numbers 6.0.7.1001 or later indicate that RealPlayer 8 is installed.

The purpose of this function is to allow you to create your own RealPlayer detection and alert system, if you do not want to use the one provided by the function `realPlayerPromptToInstall()` on page 492.

If you choose to create your own detection and alert system using the `realPlayerVersion()` function, you must do the following:

- Call `realPlayerPromptToInstall(FALSE)` (by default, this function is set to `TRUE`) before any RealMedia cast members are referenced in Lingo or appear in the Score. This function should be set in a `prepareMovie` event handler in a movie script.
- Use the `xtraList` system property to verify that the Xtra for RealMedia (RealMedia Asset.x32) is listed in the Movie Xtras dialog box. The `realPlayerVersion()` function will not work if the Xtra for RealMedia is not present.
The build number returned by this function is the same as the build number you can display in RealPlayer.

**To view the RealPlayer build number in Windows:**

1. Launch RealPlayer.
2. Choose About RealPlayer from the Help menu.
   - In the window that appears, the build number appears at the top of the screen in the second line.

**To view the RealPlayer build number on the Macintosh:**

1. Launch RealPlayer.
2. Choose About RealPlayer from the Apple menu.
   - The About RealPlayer dialog box appears. Ignore the build number listed in the second line at the top of the screen; it is incorrect.
3. Click the Version Info button.
   - The RealPlayer Version Information dialog box appears.
4. Select RealPlayer Core in the list of installed components.
   - The build number shown for RealPlayer Core component (for example, 6.0.8.1649) is the same as the build number returned by `realPlayerVersion()`.

**Parameters**

None.

**Example**

The following code shows that build number of the RealPlayer installed on the system is 6.0.9.357:

```lingo
put(realPlayerVersion())
```

```javascript
put(realPlayerVersion());
```

**recordFont**

**Usage**

`recordFont(whichCastMember, font {,[face]},{,bitmapSizes} {,characterSubset} {,userFontName})`

**Description**

Command; embeds a TrueType or Type 1 font as a cast member. Once embedded, these fonts are available to the author just like other fonts installed in the system.

You must create an empty font cast member with the `new()` command before using `recordFont`.

The command creates a Shock Font in `whichCastMember` using the font named in the `font` parameter. The value returned from the command reports whether the operation was successful. Zero indicates success.
Parameters

- **font** Required. Specifies the name of original font to be recorded.
- **face** Optional. Specifies a list of symbols indicating the face of the original font. Possible values are #plain, #bold, #italic. If you do not provide a value for this parameter, #plain is used.
- **bitmapSizes** Optional. Specifies a list of integers specifying the sizes for which bitmaps are to be recorded. This parameter can be empty. If you omit this parameter, no bitmaps are generated. These bitmaps typically look better at smaller point sizes (below 14 points) but take up more memory.
- **characterSubset** Optional. Specifies a string of characters to be encoded. Only the specified characters will be available in the font. If this parameter is omitted, all characters are encoded. If only certain characters are encoded but an unencoded character is used, that character is displayed as an empty box.
- **userFontName** Optional. Specifies a string to use as the name of the newly recorded font cast member.

Example

This statement creates a simple Shock Font using only the two arguments for the cast member and the font to record:

```lingo
myNewFontMember = new(#font)
recordFont(myNewFontMember, "Lunar Lander")
```

This statement specifies the bitmap sizes to be generated and the characters for which the font data should be created:

```lingo
myNewFontMember = new(#font)
recordFont(myNewFontMember, "lunar lander", [], [14, 18, 45], "Lunar Lander Game High \ Score First Last Name")
```

**Note:** Since `recordFont` resynthesizes the font data rather than using it directly, there are no legal restrictions on Shock Font distribution.

See also

- `newMember()`

**rect()**

Usage

- **Lingo syntax**
  ```
  rect(intLeft, intTop, intRight, intBottom)
  ```

- **JavaScript syntax**
  ```
  rect(intLeft, intTop, intRight, intBottom);
  ```

Description

Top level function; defines a rectangle.

You can perform arithmetic operations on rectangles using both Lingo and JavaScript syntax. If you add a single value to a rectangle, Lingo and JavaScript syntax adds it to each element in the rectangle.
You can refer to rectangle components by list syntax or property syntax. For example, the following assignments set both `myRectWidth1` and `myRectWidth2` to 50:

```javascript
// JavaScript syntax
var myRect = rect(40, 30, 90, 70);
var myRectWidth1 = myRect.right - myRect.left; // 50
var myRectWidth2 = myRect[3] - myRect[1]; // 50
```

To see an example of `rect()` used in a completed movie, see the Imaging movie in the Learning/Lingo folder inside the Director application folder.

### Parameters

- **intLeft** Required. An integer that specifies the number of pixels that the left side of the rectangle is from the left edge of the Stage.
- **intTop** Required. An integer that specifies the number of pixels that the top side of the rectangle is from the top edge of the Stage.
- **intRight** Required. An integer that specifies the number of pixels that the right side of the rectangle is from the left edge of the Stage.
- **intBottom** Required. An integer that specifies the number of pixels that the bottom side of the rectangle is from the top edge of the Stage.

### Example

This statement sets the variable `newArea` to a rectangle whose left side is at 100, top is at 150, right side is at 300, and bottom is at 400 pixels:

```lingo
-- Lingo syntax
newArea = rect(100, 150, 300, 400)
```

```javascript
// JavaScript syntax
var newArea = rect(100, 150, 300, 400);
```

In Lingo only, the following statement sets the variable `newArea` to the rectangle defined by the points `firstPoint` and `secondPoint`:

```lingo
-- Lingo syntax
firstPoint = point(100, 150)
secondPoint = point(300, 400)
newArea = rect(firstPoint, secondPoint)
```

In Lingo only, these statements add and subtract values for rectangles:

```lingo
-- Lingo syntax
put(rect(0, 0, 100, 100) + rect(30, 55, 120, 95)) -- rect(30, 55, 220, 195)
put(rect(0, 0, 100, 100) -rect(30, 55, 120, 95)) -- rect(-30, -55, -20, 5)
```

In Lingo only, this statement adds 80 to each coordinate in a rectangle:

```lingo
-- Lingo syntax
put(rect(60, 40, 120, 200) + 80) -- rect(140, 120, 280)
```

In Lingo only, this statement divides each coordinate in a rectangle by 3:

```lingo
-- Lingo syntax
put(rect(60, 40, 120, 200) / 3) -- rect(20, 13, 40, 66)
```

registerForEvent()

Usage

member(whichCastmember).registerForEvent(eventName, \n    handlerName, scriptObject {, begin, period, repetitions})

Description

3D command; declares the specified handler as the handler to be called when the specified event occurs within the specified cast member.

The following parameter descriptions apply to both the registerForEvent() and the registerScript() commands.

Note: You can associate the registration of a script with a particular node rather than with a cast member by using the registerScript() command.

Parameters

eventName Required. Specifies the name of the event. The event can be any of the following predefined events, or any custom event that you define:

• #collideAny is a collision event.
• #collideWith is a collision event involving this specific model. The setCollisionCallback() command is a shortcut for using the registerScript() command for the #collideWith event.
• #animationStarted and #animationEnded are notification events that occur when a bones or keyframe animation starts or stops playing. The handler will receive three arguments: eventName, motion, and time. The eventName argument is either #animationStarted or #animationEnded. The motion argument is the name of the motion that has started or stopped playing, and time is the current time of the motion.
• For looping animations, the #animationStarted event is issued only for the first loop, not for subsequent loops. During a blend of two animations, this event will be sent when the blending begins.
• When a series of animations is queued for the model and the animation’s autoBlend property is set to TRUE, the #animationEnded event may occur before the apparent end of a given motion. This is because the autoBlend property may make the motion appear to continue even though the animation has completed as defined.
• #timeMS is a time event. The first #timeMS event occurs when the number of milliseconds specified in the begin parameter have elapsed after registerForEvent is called. The period parameter determines the number of milliseconds between #timeMS events when the value of repetitions is greater then 0. If repetitions is 0, the #timeMS event occurs indefinitely.

handlerName Required. Specifies the name of the handler that will be called when the event eventName occurs; this handler is found in the script object indicated by scriptObject. The handler is sent the following arguments:

• type is always 0.
• delta is the elapsed time in milliseconds since the last #timeMS event.
• time is the number of milliseconds since the first #timeMS event occurred. For example, if there are three iterations with a period of 500 ms, the first iteration’s time will be 0, the second iteration will be 500, and the third will be 1000.
• **duration** is the total number of milliseconds that will elapse between the `registerForEvent` call and the last `#timeMS` event. For example, if there are five iterations with a period of 500 ms, the duration is 2500 ms. For tasks with unlimited iterations, the duration is 0.

• **systemTime** is the absolute time in milliseconds since the Director movie started.

  `scriptObject` Required. Specifies the script object that contains the handler `handlerName`. If 0 is specified for `scriptObject`, then the first event handler with the given name found in a movie script is called.

  `begin` Optional. Specifies the number of milliseconds after `registerForEvent()` is called that the first `#timeMS` event occurs.

  `period` Optional. Specifies the number of milliseconds between `#timeMS` events when the value of `repetitions` is greater than 0.

  `repetitions` Optional. Specifies the number of repetitions for the `#timeMS` event. If `repetitions` is 0, the `#timeMS` event occurs indefinitely.

**Example**

This statement registers the `promptUser` event handler found in a movie script to be called twice at an interval of 5 seconds:

```lisp
member("Scene").registerForEvent(#timeMS, #promptUser, 0, \ 5000, 5000, 2)
```

This statement registers the `promptUser` event handler found in a movie script to be called each time a collision occurs within the cast member named Scene:

```lisp
member("Scene").registerForEvent(#collideAny, #promptUser, 0)
```

This statement declares the `on promptUser` handler in the same script that contains the `registerForEvent` command to be called when any object collides with the model named Pluto in the cast member named Scene:

```lisp
member("Scene").registerForEvent(#collideWith, #promptUser, me, \ member("Scene").model("Pluto")
```

**See also**

`setCollisionCallback()`, `registerScript()`, `play()` (3D), `playNext()` (3D), `autoblend`, `blendTime`, `sendEvent`, `unregisterAllEvents`

**registerScript()**

**Usage**

```lisp
member(whichCastmember).model(whichModel).registerScript(eventName, \ handlerName, scriptObject {, begin, period, repetitions})
member(whichCastmember).camera(whichCamera).registerScript(eventName, \ handlerName, scriptObject {, begin, period, repetitions})
member(whichCastmember).light(whichLight).registerScript(eventName, \ handlerName, scriptObject {, begin, period, repetitions})
member(whichCastmember).group(whichGroup).registerScript(eventName, \ handlerName, scriptObject {, begin, period, repetitions})
```

**Description**

3D command; registers the specified handler to be called when the specified event occurs for the referenced node.

The following parameter descriptions apply to both the `registerForEvent()` and the `registerScript()` commands.
Parameters

**eventName** Required. Specifies the name of the event. The event can be any of the following predefined events, or any custom event that you define:

- **#collideAny** is a collision event.
- **#collideWith** is a collision event involving this specific model. The `setCollisionCallback()` command is a shortcut for using the `registerScript()` command for the **#collideWith** event.
- **#animationStarted** and **#animationEnded** are notification events that occur when a bones or keyframe animation starts or stops playing. The handler will receive three arguments: `eventName`, `motion`, and `time`. The `eventName` argument is either **#animationStarted** or **#animationEnded**. The `motion` argument is the name of the motion that has started or stopped playing, and `time` is the current time of the motion.

For looping animations, the **#animationStarted** event is issued only for the first loop, not for subsequent loops. During a blend of two animations, this event will be sent when the blending begins.

When a series of animations is queued for the model and the animation’s `autoBlend` property is set to **TRUE**, the **#animationEnded** event may occur before the apparent end of a given motion. This is because the `autoBlend` property may make the motion appear to continue even though the animation has completed as defined.

- **#timeMS** is a time event. The first **#timeMS** event occurs when the number of milliseconds specified in the `begin` parameter have elapsed after `registerForEvent()` is called. The `period` parameter determines the number of milliseconds between **#timeMS** events when the value of `repetitions` is greater than 0. If `repetitions` is 0, the **#timeMS** event occurs indefinitely.

**handlerName** Required. Specifies the name of the handler that will be called when the event `eventName` occurs; this handler is found in the script object indicated by `scriptObject`. The handler is sent the following arguments:

- **type** is always 0.
- **delta** is the elapsed time in milliseconds since the last **#timeMS** event.
- **time** is the number of milliseconds since the first **#timeMS** event occurred. For example, if there are three iterations with a period of 500 ms, the first iteration’s time will be 0, the second iteration will be 500, and the third will be 1000.
- **duration** is the total number of milliseconds that will elapse between the `registerForEvent()` call and the last **#timeMS** event. For example, if there are five iterations with a period of 500 ms, the duration is 2500 ms. For tasks with unlimited iterations, the duration is 0.
- **systemTime** is the absolute time in milliseconds since the Director movie started.

**scriptObject** Required. Specifies the script object that contains the handler `handlerName`. If 0 is specified for `scriptObject`, then the first event handler with the given name found in a movie script is called.

**begin** Optional. Specifies the number of milliseconds after `registerForEvent()` is called that the first **#timeMS** event occurs.

**period** Optional. Specifies the number of milliseconds between **#timeMS** events when the value of `repetitions` is greater than 0.

**repetitions** Optional. Specifies the number of repetitions for the **#timeMS** event. If `repetitions` is 0, the **#timeMS** event occurs indefinitely.
Example

This statement registers the `messageReceived` event handler found in a movie script to be called when the model named `Player` receives the custom user defined event named `#message`:

```plaintext
member("Scene").model("Player").registerScript(#message, \ #messageReceived, 0)
```

This statement registers the `collisionResponder` event handler found in the same script as the `registerScript` command to be called each time a collision occurs between the model named `Player` and any other model using the `#collision` modifier:

```plaintext
member("Scene").model("Player").registerScript(#collideWith, \ #collisionResponder, me)
```

See also

`registerForEvent()`, `sendEvent`, `setCollisionCallback()`

**removeBackdrop**

**Usage**

```plaintext
member(whichCastmember).camera(whichCamera).removeBackdrop(index)
```

**Description**

3D command; removes the backdrop found in a specified position from the camera’s list of backdrops to display.

**Parameters**

- `index` Required. Specifies the index position of the backdrop in the list of backdrops.

**Example**

The following statement removes the third backdrop from the list of backdrops for camera 1 within the member named `Scene`. The backdrop will disappear from the stage if there are any sprites currently using this camera.

```plaintext
member("Scene").camera[1].removeBackdrop(3)
```

**removeFromWorld**

**Usage**

```plaintext
member(whichCastmember).model(whichModel).removeFromWorld()  
member(whichCastmember).light(whichLight).removeFromWorld()  
member(whichCastmember).camera(whichCamera).removeFromWorld()  
member(whichCastmember).group(whichGroup).removeFromWorld()
```

**Description**

3D command; for models, lights, cameras or groups whose parent hierarchy terminates in the world object, this command sets their parent to void and removes them from the world.

For objects whose parent hierarchy does not terminate in the world, this command does nothing.

**Parameters**

None.
Example
This command removes the model named gbCyl from the 3D world of the cast member named Scene:
member("Scene").model("gbCyl").removeFromWorld()

removeLast()
member(whichCastmember).model(whichModel).bonesPlayer.removeLast()
member(whichCastmember).model(whichModel).keyframePlayer.
removeLast()

Description
3D keyframePlayer and bonesPlayer modifier command; removes the last motion from the modifier's playlist.

Parameters
None.

Example
This statement removes the last motion from the playlist of the bonesPlayer modifier for the model named Walker:
member("MyWorld").model("Walker").bonesPlayer.removeLast()

removeModifier

Usage
member(whichCastmember).model(whichModel).removeModifier.\n(#whichModifier)

Description
3D command; removes the specified modifier from the specified model.
This command returns TRUE if it completes successfully, and FALSE if #whichModifier is not a valid modifier, or if the modifier was not attached to the model.

Parameters
whichModifier Required. Specifies the modifier to remove.

Example
This statement removes the #toon modifier from the model named Box:
member("shapes").model("Box").removeModifier(#toon)

See also
addModifier, modifier, modifier[], modifiers
removeOverlay

Usage
member(whichCastmember).camera(whichCamera).removeOverlay(index)

Description
3D command; removes the overlay found in a specified position from the camera's list of overlays to display.

Parameters
index Required. Specifies the index position of the overlay in the list of overlays.

Example
The following statement removes the third overlay from the list of overlays for the camera being used by sprite 5. The overlay disappears from the Stage.
sprite(5).camera.removeOverlay(1)

See also
overlay

removeScriptedSprite()

Usage
-- Lingo syntax
spriteChannelObjRef.removeScriptedSprite()

// JavaScript syntax
spriteChannelObjRef.removeScriptedSprite();

Description
Sprite Channel method; switches control of a sprite channel from script back to the Score.

Parameters
None.

Example
The following statement removes the scripted sprite from sprite channel 5:
-- Lingo syntax
channel(5).removeScriptedSprite()

// JavaScript syntax
channel(5).removeScriptedSprite();

See also
makeScriptedSprite(), Sprite Channel
resetWorld

Usage

member(whichCastmember).resetWorld()
member(whichTextCastmember).resetWorld()

Description

3D command; resets the member's properties of the referenced 3D cast member to the values stored when the member was first loaded into memory. The member's state property must be either 0 (unloaded), 4 (media loaded), or -1 (error) before this command can be used, otherwise a script error will occur.

This command differs from revertToWorldDefaults in that the values used are taken from the state of the member when it was first loaded into memory rather than from the state of the member when it was first created.

Parameters

None.

Example

This statement resets the properties of the cast member named Scene to the values they had when the member was first loaded into memory:
member("Scene").resetWorld()

See also

revertToWorldDefaults

resolveA

Usage

collisionData.resolveA(bResolve)

Description

3D collision method; overrides the collision behavior set by the collision.resolve property for collisionData.modelA. Call this function only if you wish to override the behavior set for modelA using collision.resolve.

Parameters

bResolve Required. Specifies whether the collision for modelA is resolved. If bResolve is TRUE, then the collision for the modelA is resolved; if bResolve is FALSE the collision for modelA is not resolved.

See also

collisionData, registerScript(), resolve, modelA, setCollisionCallback()
resolveB

Usage

collisionData.resolveB(bResolve)

Description

3D collision method; overrides the collision behavior set by the collision.resolve property for collisionData.modelB. Call this function only if you wish to override the behavior set for modelB using collision.resolve.

Parameters

bResolve Required. Specifies whether the collision for modelB is resolved. If bResolve is TRUE, then the collision for the modelB is resolved; if bResolve is FALSE the collision for modelB is not resolved.

See also

collisionData, resolve, registerScript(), modelB, setCollisionCallback()

restart()

Usage

-- Lingo syntax
_system.restart()

// JavaScript syntax
_system.restart();

Description

System method; closes all open applications and restarts the computer.

Parameters

None.

Example

This statement restarts the computer when the user presses Command+R (Macintosh) or Control+R (Windows):

-- Lingo syntax
if (_key.key = "r" and _key.commandDown) then
_system.restart()
end if

// JavaScript syntax
if (_key.key = "r" && _key.commandDown) {
_system.restart();
}

See also

System
restore()

Usage
-- Lingo syntax
windowObjRef.restore()

// JavaScript syntax
windowObjRef.restore();

Description
Window method; restores a window after it has been maximized.
Use this method when making custom titlebars for movies in a window (MIAW).

Parameters
None.

Example
This statement restores the maximized window named Control Panel:

-- Lingo syntax
window("Control Panel").restore()

// JavaScript syntax
window("Control Panel").restore();

See also
maximize(), Window

result

Usage
the result

Description
Function; displays the value of the return expression from the last handler executed.
The result function is useful for obtaining values from movies that are playing in windows and tracking Lingo’s progress by displaying results of handlers in the Message window as the movie plays.
To return a result from a handler, assign the result to a variable and then check the variable’s value. Use a statement such as set myVariable = function(), where function() is the name of a specific function.

Parameters
None.

Example
This handler returns a random roll for two dice:

on diceRoll
  return random(6) + random(6)
end
In the following example, the two statements

```markdown
diceRoll
roll = the result
```

are equivalent to this statement:

```markdown
set roll = diceRoll()
```

The statement `set roll = diceRoll` would not call the handler because there are no parentheses following `diceRoll`; `diceRoll` here is considered a variable reference.

See also
return (keyword)

**resume()**

**Usage**

```markdown
-- Lingo syntax
animGifSpriteRef.resume()

// JavaScript syntax
animGifSpriteRef.resume();
```

**Description**

Animated GIF method; causes the sprite to resume playing from the frame after the current frame if it’s been paused. This command has no effect if the animated GIF sprite has not been paused.

**Parameters**
None.

See also
rewind() (Animated GIF, Flash)

**returnToTitle()**

**Usage**

```markdown
-- Lingo syntax
dvdObjRef.returnToTitle()

// JavaScript syntax
dvdObjRef.returnToTitle();
```

**Description**

DVD method; resumes playback after a menu has been displayed.

**Parameters**
None.
Example
This statement resumes playback after a menu has been displayed:

```lua
-- Lingo syntax
member(1).returnToTitle()
```

```javascript
// JavaScript syntax
member(1).returnToTitle();
```

See also
DVD

revertToWorldDefaults

Usage
```
member(whichCastmember).revertToWorldDefaults()
```

Description
3D command; reverts the properties of the specified 3D cast member to the values stored when the member was first created. The member's `state` property must be 4 (loaded) or -1 (error) before this command can be used, otherwise a script error will occur.

This command differs from `resetWorld` in that the values used are taken from the state of the member when it was first created rather than from the state of the member when it was first loaded into memory.

Parameters
None.

Example
This statement reverts the properties of the cast member named Scene to the values stored when the member was first created:
```
member("Scene").revertToWorldDefaults()
```

See also
`resetWorld`

rewind() (Sound Channel)

Usage
```
-- Lingo syntax
soundChannelObjRef.rewind()
```

```javascript
// JavaScript syntax
soundChannelObjRef.rewind();
```

Description
Sound Channel method; interrupts the playback of the current sound in a sound channel and restarts it at its `startTime`.

If the sound is paused, it remains paused, with the `currentTime` set to the `startTime`. 
Parameters
None.

Example
This statement restarts playback of the sound cast member playing in sound channel 1 from the beginning:

-- Lingo syntax
sound(1).rewind()

// JavaScript syntax
sound(1).rewind();

See also
Sound Channel, startTime

rewind() (Windows Media)

Usage

-- Lingo syntax
windowsMediaObjRef.rewind()

// JavaScript syntax
windowsMediaObjRef.rewind();

Description
Windows Media cast member or sprite method. Rewinds to the first frame of a Windows Media cast member or sprite.

Calling this method has no effect on the `mediaStatus`.

Parameters
None.

See also
mediaStatus (RealMedia, Windows Media), Windows Media

rewind() (Animated GIF, Flash)

Usage

-- Lingo syntax
animGifSpriteRef.rewind()

// JavaScript syntax
animGifSpriteRef.rewind();

Description
Command; returns a Flash or animated GIF movie sprite to frame 1 when the sprite is stopped or when it is playing.

Parameters
None.
Example

The following frame script checks whether the Flash movie sprite in the sprite the behavior was placed in is playing and, if so, continues to loop in the current frame. When the movie is finished, the sprite rewinds the movie (so the first frame of the movie appears on the Stage) and lets the playhead continue to the next frame.

```
-- Lingo syntax
property spriteNum

on exitFrame
    if sprite(spriteNum).playing then
        _movie.go(_movie.frame)
    else
        sprite(spriteNum).rewind()
        _movie.updateStage()
    end if
end

// JavaScript syntax
function exitFrame() {
    var plg = sprite(this.spriteNum).playing;
    if (plg = 1) {
        _movie.go(_movie.frame);
    } else {
        sprite(this.spriteNum).rewind();
        _movie.updateStage();
    }
}
```

rollOver()

Usage

```
-- Lingo syntax
_movie.rollOver({intValue})

// JavaScript syntax
_movie.rollOver({intValue});
```

Description

Movie method; indicates whether the pointer (cursor) is currently over the bounding rectangle of a specified sprite (TRUE or 1) or not (FALSE or 0).

The rollOver() method is typically used in frame scripts and is useful for creating handlers that perform an action when the user places the pointer over a specific sprite.

If the user continues to roll the mouse, the value of rollOver() can change while a script is running a handler, and can result in unexpected behavior. You can make sure that a handler uses a consistent rollover value by assigning rollOver() to a variable when the handler starts.

When the pointer is over an area of the Stage where a sprite previously appeared, rollOver() still occurs and reports the sprite as still being there. Avoid this behavior by not performing rollovers over these locations, or by moving the sprite above the menu bar before removing it.

Parameters

intValue Optional. An integer that specifies the sprite number.
Example

This statement changes the content of the field cast member Message to “This is the place.” when the pointer is over sprite 6:

-- Lingo syntax
if (_movie.rollOver(6)) then
    member("Message").text = "This is the place."
end if

// JavaScript syntax
if (_movie.rollOver(6)) {
    member("Message").text = "This is the place."
}

The following handler sends the playhead to different frames when the pointer is over certain sprites on the Stage. It first assigns the rollOver value to a variable. This lets the handler use the rollOver value that was in effect when the rollover started, regardless of whether the user continues to move the mouse.

-- Lingo syntax
on exitFrame
    currentSprite = _movie.rollOver()
    case currentSprite of
        1: _movie.go("Left")
        2: _movie.go("Middle")
        3: _movie.go("Right")
    end case
end exitFrame

// JavaScript syntax
function exitFrame() {
    var currentSprite = _movie.rollOver();
    switch (currentSprite) {
        case 1: _movie.go("Left");
            break;
        case 2: _movie.go("Middle");
            break;
        case 3: _movie.go("Right");
            break;
    }
}

Movie

rootMenu()

Usage

-- Lingo syntax
dvdObjRef.rootMenu()

// JavaScript syntax
dvdObjRef.rootMenu();

Description

DVD method; displays the root menu.
Parameters

None.

See also

DVD

rotate

Usage

member(whichCastmember).node(whichNode).rotate(xAngle, yAngle, \n zAngle [, relativeTo])
member(whichCastmember).node(whichNode).rotate(rotationVector \n 1, relativeTo)
member(whichCastmember).node(whichNode).rotate(position, axis, \n 1 angle [, relativeTo])
transform.rotate(xAngle, yAngle, zAngle [, relativeTo])
transform.rotate(rotationVector [, relativeTo])
transform.rotate(position, axis, angle [, relativeTo])

Description

3D command; applies a rotation after the current positional, rotational, and scale offsets held by
the node's transform object or the directly referenced transform object. The rotation must be
specified as a set of three angles, each of which specify an angle of rotation about the three
corresponding axes. These angles may be specified explicitly in the form of xAngle, yAngle, and
zAngle, or by a rotationVector, where the x component of the vector corresponds to the
rotation about the X axis, y about Y axis, and z about Z axis. Alternatively, the rotation may also
be specified as a rotation about an arbitrary axis passing through a point in space.

Parameters

xAngle Required if applying a rotation using x-, y-, and z-axes. Specifies the angle of rotation
about the x-axis.
yAngle Required if applying a rotation using x-, y-, and z-axes. Specifies the angle of rotation
about the y-axis.
zAngle Required if applying a rotation using x-, y-, and z-axes. Specifies the angle of rotation
about the z-axis.
rotationVector Required if applying a rotation using a vector. Specifies the vector that contains
the angles to apply.
position Required if applying a rotation about an arbitrary axis passing through a point in space.
Specifies position in space.
axis Required if applying a rotation about an arbitrary axis passing through a point in space.
Specifies the axis passing through the specified position position.
angle Required if applying a rotation about an arbitrary axis passing through a point in space.
Specifies the amount of rotation about the axis axis.
**relativeTo** Optional. Specifies which coordinate system axes are used to apply the desired rotational changes. The **relativeTo** parameter can have any of the following values:

- **#self** applies the increments relative to the node’s local coordinate system (the X, Y and Z axes specified for the model during authoring). This value is used as the default if you use the rotate command with a node reference and the **relativeTo** parameter is not specified.
- **#parent** applies the increments relative to the node’s parent’s coordinate system. This value is used as the default if you use the rotate command with a transform reference and the **relativeTo** parameter is not specified.
- **#world** applies the increments relative to the world coordinate system. If a model’s parent is the world, than this is equivalent to using **#parent**.
- **nodeReference** allows you to specify a node to base your rotation upon, the command applies the increments relative to the coordinate system of the specified node.

**Example**

The following example first rotates the model named Moon about its own Z axis (rotating it in place), then it rotates that same model about its parent node, the model named Earth (causing Moon to move orbitally about Earth).

```plaintext
member("Scene").model("Moon").rotate(0,0,15)
member("Scene").model("Moon").rotate(vector(0, 0, 5),
member("Scene").model("Moon"))
```

The following example rotates the model Ball around a position in space occupied by the model named Pole. The effect is that the model Ball moves in orbit around Pole in the x-y plane.

```plaintext
polePos = member("3d Scene").model("Pole").worldPosition
member("3d Scene").model("Ball").rotate(polePos, vector(0,0,1),
8, #world)
```

**See also**

pointAt, preRotate, rotation (transform), rotation (engraver shader), rotation (backdrop and overlay), preScale(), transform (property)

---

**runMode**

**Usage**

the runMode

**Description**

Function; returns a string indicating the mode in which the movie is playing. Possible values are as follows:

- **Author**—The movie is running in Director.
- **Projector**—The movie is running as a projector.
- **BrowserPlugin**—The movie is running as a Shockwave Player plug-in or other scripting environment, such as LiveConnect or ActiveX.

The safest way to test for particular values in this property is to use the contains operator. This helps avoid errors and allows partial matches.

**Parameters**

None.
Example

This statement determines whether or not external parameters are available and obtains them if they are:

--Lingo syntax
if the runMode contains "Plugin" then
  -- decode the embed parameter
  if externalParamName(swURL) = swURL then
    put externalParamValue(swURL) into myVariable
  end if
end if

// JavaScript syntax
if (_movie.runMode.indexOf("Plugin") >=0) {
  // decode the embed parameter
  if (externalParamName(swURL) == swURL) {
    myVariable = externalParamValue(swURL);
  }
}

See also
environmentPropList, platform

save castLib

Usage
save castLib( whichCast ).save()
save castLib whichCast {}

Description
Command; saves changes to the cast in the cast’s original file or in a new file. Further operations or references to the cast use the saved cast member.

This command does not work with compressed files.

The save CastLib command doesn’t support URLs as file references.

Parameters

pathName&newFileName Optional. Specifies the path and file name to save to. If omitted, the original cast must be linked.

Example

This statement causes Director to save the revised version of the Buttons cast in the new file UpdatedButtons in the same folder:
castLib("Buttons").save( the moviePath & "UpdatedButtons.cst" )

See also
@ (pathname)
saveMovie()

Usage

-- Lingo syntax
_movie.saveMovie({stringFilePath})

// JavaScript syntax
_movie.saveMovie({stringFilePath});

Description

Movie method; saves the current movie.

Including the optional stringFilePath parameter saves the movie to the file specified. This method does not work with compressed files. The specified filename must include the .dir file extension.

The saveMovie() method doesn’t support URLs as file references.

Parameters

stringFilePath Optional. A string that specifies the path to and name of the file to which the movie is saved.

Example

This statement saves the current movie in the Update file:

-- Lingo syntax
_movie.saveMovie(_movie.path & "Update.dir")

// JavaScript syntax
_movie.saveMovie(_movie.path + "Update.dir");

See also

Movie

scale (command)

Usage

member(whichCastmember).node(whichNode).scale(xScale, yScale, zScale)
member(whichCastmember).node(whichNode).scale(uniformScale)
transform.scale(xScale, yScale, zScale)
transform.scale(uniformScale)

Description

3D transform command; applies a scaling after the current positional, rotational, and scale offsets held by a referenced node's transform or the directly referenced transform. The scaling must be specified as either a set of three scalings along the corresponding axes or as a single scaling to be applied uniformly along all axes. You can specify the individual scalings using the xScale, yScale and zScale parameters, otherwise you can specify the uniform scaling amount using the uniformScale parameter.

A node can be a camera, group, light or model object. Using the scale command adjusts the referenced node's transform.scale property, but it does not have any visual effect on lights or cameras as they do not contain geometry.

The scaling values provided must be greater than zero.
Parameters

- **xScale**: Required if specifying three scalings. Specifies the scale along the x-axis.
- **yScale**: Required if specifying three scalings. Specifies the scale along the y-axis.
- **zScale**: Required if specifying three scalings. Specifies the scale along the z-axis.
- **uniformScale**: Required if specifying a single, uniform scaling. Specifies the uniform scaling.

Example

This example first displays the `transform.scale` property for the model named Moon, then it scales the model using the `scale` command, and finally, it displays the resulting `transform.scale` value.

```
put member("Scene").model("Moon").transform.scale
   -- vector( 1.0000, 1.0000, 1.0000)
member("Scene").model("Moon").scale(2.0,1.0,0.5)
put member("Scene").model("Moon").transform.scale
   -- vector( 2.0000, 1.0000, 0.5000)
```

This statement scales the model named Pluto uniformly along all three axes by 0.5, resulting in the model displaying at half of its size.

```
member("Scene").model("Pluto").scale(0.5)
```

This statement scales the model named Oval in a nonuniform manner, scaling it along its z-axis but not its x- or y-axes.

```
member("Scene").model("Pluto").scale(0.0, 0.0, 0.5)
```

See also

- `transform (property)`, `preScale()`, `scale (transform)`

script()

Usage

- **Lingo syntax**

  ```
  script(memberNameOrNum [, castNameOrNum])
  // JavaScript syntax
  script(memberNameOrNum [, castNameOrNum]);
  ```

Description

Top level function; creates a reference to a given cast member that contains a script, and optionally specifies the cast library that contains the member.

An error is returned if the given cast member does not contain a script, or if the given cast member does not exist.

Parameters

- **memberNameOrNum**: Required. A string that specifies the name of the cast member that contains a script, or an integer that specifies the index position of the cast member that contains a script.
- **castNameOrNum**: Optional. A string that specifies the name of the cast library that contains the member `memberNameOrNum`, or an integer that specifies the index position of the cast library that contains the member `memberNameOrNum`. If omitted, `script()` searches the first cast library.
Example

In Lingo only, these statements check whether a child object is an instance of the parent script Warrior Ant:

--- Lingo syntax
if (bugObject.script = script("Warrior Ant")) then
  bugObject.attack()
end if

This statement sets the variable actionMember to the script cast member Actions:

--- Lingo syntax
actionMember = script("Actions")

// JavaScript syntax
var actionMember = script("Actions");

scrollByLine()

Usage

--- Lingo syntax
memberObjRef.scrollByLine(amount)

// JavaScript syntax
memberObjRef.scrollByLine(amount);

Description

Command; scrolls the specified field or text cast member up or down by a specified number of lines. Lines are defined as lines separated by carriage returns or by wrapping.

Parameters

amount Required. Specifies the number of lines to scroll. When amount is positive, the field scrolls down. When amount is negative, the field scrolls up.

Example

This statement scrolls the field cast member Today's News down five lines:

---Lingo syntax
member("Today's News").scrollByLine(5)

// JavaScript syntax
member("Today's News").scrollByLine(5);

This statement scrolls the field cast member Today's News up five lines:

---Lingo syntax
member("Today's News").scrollByLine(-5)

// JavaScript syntax
member("Today's News").scrollByLine(-5);
scrollByPage()

Usage

-- Lingo syntax
memberObjRef.scrollByPage(amount)

// JavaScript syntax
memberObjRef.scrollByPage(amount);

Description

Command; scrolls the specified field or text cast member up or down by a specified number of pages. A page is equal to the number of lines of text visible on the screen.

Parameters

amount Required. Specifies the number of pages to scroll. When amount is positive, the field scrolls down. When amount is negative, the field scrolls up.

Example

This statement scrolls the field cast member Today's News down one page:

--Lingo syntax
member("Today's News").scrollbypage(1)

// JavaScript syntax
member("Today's News").scrollbypage(1);

This statement scrolls the field cast member Today's News up one page:

--Lingo syntax
member("Today's News").scrollbypage(-1)

// JavaScript syntax
member("Today's News").scrollbypage(-1);

See also

scrollTop

seek()

Usage

-- Lingo syntax
memberOrSpriteObjRef.seek(milliseconds)

// JavaScript syntax
memberOrSpriteObjRef.seek(milliseconds);

Description

RealMedia sprite or cast member method; changes the media stream's playback location to the location specified by the number of milliseconds from the beginning of the stream. The mediaStatus value usually becomes #seeking and then #buffering.

You can use this method to initiate play at points other than the beginning of the RealMedia stream, or to jump forward or backward in the stream. The integer specified in milliseconds is the number of milliseconds from the beginning of the stream; thus, to jump backward, you would specify a lower number of milliseconds, not a negative number.
If the `seek` command is called when `mediaStatus` is `#paused`, the stream rebuffers and returns to `#paused` at the new location specified by `seek`. If `seek` is called when `mediaStatus` is `#playing`, the stream rebuffers and automatically begins playing at the new location in the stream. If `seek` is called when `mediaStatus` is `#closed`, nothing happens.

If you attempt to seek beyond the stream’s `duration` value, the integer argument you specify is clipped to the range from 0 to the duration of the stream. You cannot jump ahead into a RealMedia sprite that is streaming live content.

The statement `x.seek(n)` is the same as `x.currentTime = n`, and either of these calls will cause the stream to be rebuffed.

**Parameters**

- `milliseconds` **Required.** An integer that specifies the number of milliseconds from the beginning of the stream.

**Example**

The following examples set the current playback position of the stream to 10,000 milliseconds (10 seconds):

```
-- Lingo syntax
sprite(2).seek(10000)
member("Real").seek(10000)

// JavaScript syntax
sprite(2).seek(10000);
member("Real").seek(10000);
```

**See also**

`duration (RealMedia, SWA)`, `currentTime (RealMedia)`, `play() (RealMedia, SWA, Windows Media)`, `pause() (RealMedia, SWA, Windows Media)`, `stop() (RealMedia, SWA, Windows Media)`, `mediaStatus (RealMedia, Windows Media)`

### selectAtLoc()

**Usage**

```
-- Lingo syntax
dvdObjRef.selectAtLoc(point(x, y))

// JavaScript syntax
dvdObjRef.selectAtLoc(point(x, y));
```

**Description**

DVD method; initiates the button under a specified point.

This method has the same functionality as a mouse click on a button.

**Parameters**

- `point(x, y)` **Required.** A point that specifies the location under which a button is initiated.
Example

This statement initiates the button under a specified point:

```-- Lingo syntax
member(10).selectAtLoc(point(50, 75))
// JavaScript syntax
member(10).selectAtLoc(point(50, 75));```

See also
-- DVD

selectButton()

Usage

```-- Lingo syntax
dvdObjRef.selectButton(intButton)
// JavaScript syntax
dvdObjRef.selectButton(intButton);```

Description

DVD method; selects a specified button.

This method returns TRUE (1) if successful.

Parameters

`intButton` Required. An integer that specifies the button to select.

Example

This statement selects button 5:

```-- Lingo syntax
sprite(11).selectButton(5)
// JavaScript syntax
sprite(11).selectButton(5);```

See also
-- DVD

selectButtonRelative()

Usage

```-- Lingo syntax
dvdObjRef.selectButtonRelative(direction)
// JavaScript syntax
dvdObjRef.selectButtonRelative(direction);```

Description

DVD method; selects a button relative to the current button position in the menu.
Parameters

direction Required. A symbol (Lingo) or a string (JavaScript syntax) that specifies the direction to move from the current button position. Valid values are left or right.

Example

This statement specifies the button to the left of the current button:

-- Lingo syntax
sprite(12).member.selectButtonRelative(#left)

// JavaScript syntax
sprite(12).member.selectButtonRelative("left");

See also

DVD

selection() (function)

Usage

the selection

Description

Function; returns a string containing the highlighted portion of the current editable field. This function is useful for testing what a user has selected in a field.

The selection function only indicates which string of characters is selected; you cannot use selection to select a string of characters.

Parameters

None.

Example

This statement checks whether any characters are selected and, if none are, displays the alert “Please select a word.”:

if the selection = EMPTY then alert "Please select a word."

See also

selStart, selEnd

sendAllSprites()

Usage

-- Lingo syntax
_movie.sendAllSprites(stringEventMessage [, args])

// JavaScript syntax
_movie.sendAllSprites(stringEventMessage [, args]);

Description

Movie method; sends a designated message to all sprites, not just the sprite that was involved in the event. As with any other message, the message is sent to every script attached to the sprite, unless the stopEvent() method is used.
For best results, send the message only to those sprites that will properly handle the message through the `sendSprite()` method. No error will occur if the message is sent to all the sprites, but performance may decrease. There may also be problems if different sprites have the same handler in a behavior, so avoid conflicts by using unique names for messages that will be broadcast.

After the message has been passed to all behaviors, the event follows the regular message hierarchy: cast member script, frame script, then movie script.

When you use the `sendAllSprites()` method, be sure to do the following:

- Replace `stringEventMessage` with the message.
- Replace `args` with any arguments to be sent with the message.

If no sprite has an attached behavior containing the given handler, `sendAllSprites()` returns `FALSE`.

**Parameters**

- `stringEventMessage` Required. A string that specifies the message to send to all sprites.
- `args` Optional. An argument or arguments to send with the message.

**Example**

This handler sends the custom message `allSpritesShouldBumpCounter` and the argument 2 to all sprites when the user clicks the mouse:

```-- Lingo syntax
on mouseDown me
_movie.sendAllSprites(#allspritesShouldBumpCounter, 2)
end

// JavaScript syntax
function mouseDown() {
_movie.sendAllSprites("allspritesShouldBumpCounter", 2);
}
```

**See also**

`Movie`, `sendSprite()`, `stopEvent()`

**sendEvent**

**Usage**

`member(whichCastmember).sendEvent(#eventName, arg1, arg2,...)`

**Description**

3D command; sends an event and an arbitrary number of arguments to all scripts registered to receive the event. Use `registerForEvent()`, or `setCollisionCallback()` to register scripts for events.

**Parameters**

- `eventName` Required. Specifies the name of the event to send.
- `arg1, arg2, ...` Required. One or more arguments that are sent with the event `eventName`. 
Example

The first line in this example creates an instance of a parent script named "tester". The second line sets the handler of the script instance, jumpPluto, as the handler to be called when the #jump event is sent. The third line registers a movie script handler named jumpMars as another handler to be called when the #jump event is sent. The fourth line sends the #jump event. The handlers #jumpMars in a movie script and #jumpPluto are called, along with any other handlers registered for the #jump event. A script instance value of 0 indicates that you are registering a handler of a movie script, as opposed to a handler of a behavior instance or of a child of a parent script.

```
t = new (script "tester")
member("scene").registerForEvent(#jump, #jumpPluto, t)
member("scene").registerForEvent(#jump, #jumpMars, 0)
member("scene").sendEvent(#jump)
```

See also
registerScript(), registerForEvent(), setCollisionCallback()

sendSprite()

Usage

-- Lingo syntax
_movie.sendSprite(spriteNameOrNum, event[, args])

// JavaScript syntax
_movie.sendSprite(spriteNameOrNum, event[, args]);

Description

Movie method; sends a message to all scripts attached to a specified sprite. Messages sent using sendSprite() are sent to each of the scripts attached to the sprite. The messages then follow the regular message hierarchy: cast member script, frame script, and movie script.

If the given sprite does not have an attached behavior containing the given handler, sendSprite() returns FALSE.

Parameters

spriteNameOrNum Required. A string or an integer that specifies the name or number of the sprite that will receive the event.

event Required. A symbol or string that specifies the event to send to the specified sprite.

args Optional. An argument or arguments to send with the message.

Example

This handler sends the custom message bumpCounter and the argument 2 to sprite 1 when the user clicks:

```
-- Lingo syntax
on mouseDown me
    _movie.sendSprite(1, #bumpCounter, 2)
end

// JavaScript syntax
function mouseDown() {
    _movie.sendSprite(1, "bumpCounter", 2);
}
```
setAlpha()

Usage

```lingo
imageObject.setAlpha(alphaLevel)
imageObject.setAlpha(alphaImageObject)
```

Description

Function; sets the alpha channel of an image object to a flat alphaLevel or to an existing alphaImageObject. The alphaLevel must be a number from 0–255. Lower values cause the image to appear more transparent. Higher values cause the image to appear more opaque. The value 255 has the same effect as a value of zero. In order for the alphaLevel to have effect, the useAlpha() of the image object must be set to TRUE.

The image object must be 32-bit. If you specify an alpha image object, it must be 8-bit. Both images must have the same dimensions. If these conditions are not met, setAlpha() has no effect and returns FALSE. The function returns TRUE when it is successful.

Example

The following Lingo statement makes the image of the bitmap cast member Foreground opaque and disables the alpha channel altogether. This is a good method for removing the alpha layer from an image:

```lingo
member("Foreground").image.setAlpha(255)
member("Foreground").image.useAlpha = FALSE
```

This Lingo gets the alpha layer from the cast member Sunrise and places it into the alpha layer of the cast member Sunset:

```lingo
tempAlpha = member("Sunrise").image.extractAlpha()
member("Sunset").image.setAlpha(tempAlpha)
```

See also

useAlpha, extractAlpha()

setaProp

Usage

```lingo
setaProp list, listProperty, newValue
setaProp (childObject, listProperty, newValue)
list.[listProperty] = newValue
childObject.listProperty = newValue
```

Description

Command; replaces the value assigned to listProperty with the value specified by newValue. The setaProp command works with property lists and child objects. Using setaProp with a linear list produces a script error.

- For property lists, setaProp replaces a property in the list specified by list. When the property isn't already in the list, Lingo adds the new property and value.
- For child objects, setaProp replaces a property of the child object. When the property isn't already in the object, Lingo adds the new property and value.
The `setaProp` command can also set ancestor properties.

**Parameters**

- `listProperty` Required. A symbol (Lingo only) or a string that specifies the name of the property whose value is changing.
- `newValue` Required. The new value for the `listProperty` property.

**Example**

These statements create a property list and then adds the item `#c:10` to the list:

```lisp
newList = [#a:1, #b:5]
put newList
-- [#a:1, #b:5]
setaProp newList, #c, 10
put newList
```

Using the dot operator, you can alter the property value of a property already in a list without using `setaProp`:

```lisp
newList = [#a:1, #b:5]
put newList
-- [#a:1, #b:5]
newList.b = 99
put newList
-- [#a:1, #b:99]
```

**Note:** To use the dot operator to manipulate a property, the property must already exist in the list, child object, or behavior.

**See also**

- `ancestor`, `property`, `. (dot operator)`

### setAt

**Usage**

```
setAt list, orderNumber, value
```

**Description**

Command; replaces the item specified by `orderNumber` with the value specified by `value` in the list specified by `list`. When `orderNumber` is greater than the number of items in a property list, the `setAt` command returns a script error. When `orderNumber` is greater than the number of items in a linear list, Director expands the list’s blank entries to provide the number of places specified by `orderNumber`.

**Example**

This handler assigns a name to the list `[12, 34, 6, 7, 45]`, replaces the fourth item in the list with the value 10, and then displays the result in the Message window:

```lisp
on enterFrame
  set vNumbers = [12, 34, 6, 7, 45]
  setAt vnumbers, 4, 10
  put vNumbers
end enterFrame
```
When the handler runs, the Message window displays the following:

[12, 34, 6, 10, 45]

You can perform this same operation may be done using bracket access to the list in the following manner:

```plaintext
on enterFrame
    set vNumbers = [12, 34, 6, 7, 45]
    vNumbers[4] = 10
    put vNumbers
end enterFrame
```

When the handler runs, the Message window displays the following:

[12, 34, 6, 10, 45]

See also

[ ] (bracket access)

**setCallback()**

**Usage**

-- Lingo syntax
```
spriteObjRef.setCallback(actionScriptObject, ASEventName, #LingoHandlerName, \n    lingoScriptObject)
```

// JavaScript syntax
```
spriteObjRef.setCallback(actionScriptObject, ASEventName, #LingoHandlerName, \n    lingoScriptObject);
```

**Description**

Flash command; this command can be used as a sprite or a global method to define a Lingo callback handler for a particular event generated by the specified object. When ActionScript triggers the event in the object, that event is redirected to the given Lingo handler, including all arguments that are passed with the event.

If the ActionScript object was originally created within a Flash sprite, use the *flashSpriteReference* syntax. If the object was originally created globally, use the global syntax.

**Note:** If you have not imported any Flash cast members, you must manually add the Flash Asset Xtra to your movie’s Xtra list in order for global Flash commands to work correctly. You add Xtra extensions to the Xtra list by choosing **Modify > Movie > Xtras**. For more information about managing Xtra extensions for distributed movies, see the Using Director topics in the Director Help Panel.

**Parameters**

- `actionScriptObject` **Required.** Specifies the ActionScript object that contains the event `ASEventName`.
- `ASEventName` **Required.** Specifies the ActionScript event that occurs.
- `LingoHandlerName` **Required.** Specifies the Lingo handler that handles the event `ASEventName`.
- `lingoScriptObject` **Required.** Specifies the Lingo script object that contains the handler `LingoHandlerName`. 
Example

This statement sets a the Lingo handler named myOnStatus in the Lingo script object me to be called when an onStatus event is generated by the ActionScript object tLocalConObject in the Flash movie in sprite 3:

```lingo
-- Lingo syntax
sprite(3).setCallback(tLocalConObject, "onStatus", #myOnStatus, me)
```

```javascript
// JavaScript syntax
sprite(3).setCallback(tLocalConObject, "onStatus", symbol("myOnStatus"), me);
```

The following statements create a new global XML object and create a callback handler that parses XML data when it arrives. The third line loads an XML file. The callback handler is included as well.

```lingo
-- Lingo syntax
gXMLCB = newObject("XML")
setCallback( gXMLCB, "onData", #dataFound, 0 )
gXMLCB.load( "myfile.xml" )
```

```javascript
// JavaScript syntax
gXMLCB = newObject("XML");
setCallback( gXMLCB, "onData", symbol("dataFound"), 0 );
gXMLCB.load( "myfile.xml" );
```

```lingo
-- Callback handler invoked when xml data arrives
on dataFound me, obj, source
  obj.parseXML(source)
  obj.loaded = 1
  obj.onload(TRUE)
end dataFound
```

```javascript
// Callback handler invoked when xml data arrives
function dataFound(me, obj, source) {
  obj.parseXML(source);
  obj.loaded = 1;
  obj.onload(1);
}
```

See also

newObject(), clearAsObjects()

setCollisionCallback()

Usage

```lingo
member(whichCastmember).model(whichModel).collision.
  setCollisionCallback (#handlerName, scriptInstance)
```

Description

3D collision command; registers a specified handler, in a given script instance, to be called when whichModel is involved in a collision.

This command works only if the model's collision.enabled property is TRUE. The default behavior is determined by the value of collision.resolve, you can override it using the collision.resolveA and/or the collision.resolveB commands. Do not use the updateStage command in the specified handler.
This command is a shorter alternative to using the `registerScript` command for collisions, but there is no difference in the overall result. This command can be considered to perform a small subset of the `registerScript` command functionality.

**Parameters**

- **handlerName** Required. Specifies the handler called when a model is involved in a collision.
- **scriptInstance** Required. Specifies the script instance that contains the handler specified by `handlerName`.

**Example**

This statement causes the `#bounce` handler in the cast member `colScript` to be called when the model named `Sphere` collides with another model:

```lingo
member("3d world").model("Sphere").collision.
  setCollisionCallback
  (#bounce, member("colScript"))
```

**See also**

- `collisionData`, `collision (modifier)`, `resolve`, `resolveA`, `resolveB`, `registerForEvent()`, `registerScript()`, `sendEvent`

### setFilterMask()

**Usage**

```lingo
-- Lingo syntax
fileioObjRef.setFilterMask(stringMask)
```

```javascript
// JavaScript syntax
fileioObjRef.setFilterMask(stringMask);
```

**Description**

Fileio method; Sets the filter mask for the `Files of type` field of a dialog box to specify the type of files displayed when the dialog box opens.

**Parameters**

- **stringMask** Required. A string that specifies the filter mask.

**See also**

- `Fileio`

### setFinderInfo()

**Usage**

```lingo
-- Lingo syntax
fileioObjRef.setFinderInfo(stringAttrs)
```

```javascript
// JavaScript syntax
fileioObjRef.setFinderInfo(stringAttrs);
```

**Description**

Fileio method (Macintosh only); Sets the finder information for an open file.
setFlashProperty()

Usage

-- Lingo syntax
spriteObjRef.setFlashProperty(targetName, #property, newValue)

// JavaScript syntax
spriteObjRef.setFlashProperty(targetName, #property, newValue);

Description

Function; allows Lingo to call the Flash action script function setProperty() on the given Flash sprite. Use the setFlashProperty() function to set the properties of movie clips or levels within a Flash movie. This is similar to setting sprite properties within Director.

To set a global property of the Flash sprite, pass an empty string as the targetName. You can set the global Flash properties: #focusRect and #spriteSoundBufferTime.

See the Flash documentation for descriptions of these properties.

Parameters

targetName Required. Specifies the name of the movie clip or level whose property you want to set within the given Flash sprite.

property Required. Specifies the name of the property to set. You can set the following movie clip properties: #posX, #posY, #scaleX, #scaleY, #visible, #rotate, #alpha, and #name.

newValue Required. Specifies the new value.

Example

This statement sets the value of the #rotate property of the movie clip Star in the Flash member in sprite 3 to 180:

-- Lingo syntax
sprite(3).setFlashProperty("Star", #rotate, 180)

// JavaScript syntax
sprite(3).setFlashProperty("Star", symbol("rotate"), 180);

See also

getchFlashProperty()
setNewLineConversion()

Usage

```
-- Lingo syntax
fileioObjRef.setNewLineConversion(intOnOff)

// JavaScript syntax
fileioObjRef.setNewLineConversion(intOnOff)
```

Description

Fileio method (Macintosh only); Specifies whether automatic conversion of new line characters is on or off.

Parameters

`intOnOff` Required. An integer that specifies whether automatic conversion is on or off. Valid values include 0 (off) or 1 (on).

See also

Fileio

setPixel()

Usage

```
-- Lingo syntax
imageObjRef.setPixel(x, y, colorObjOrIntValue)
imageObjRef.setPixel(point(x, y), colorObjOrIntValue)

// JavaScript syntax
imageObjRef.setPixel(x, y, colorObjOrIntValue);
imageObjRef.setPixel(point(x, y), colorObjOrIntValue);
```

Description

Image method. Sets the color value of the pixel at a specified point in a given image.

If setting many pixels to the color of another pixel with `getPixel()`, it is faster to set them as integers.

For best performance with color objects, use an indexed color object with 8-bit or lower images, and use an RGB color object with 16-bit or higher images.

This method returns FALSE if the specified pixel falls outside the specified image.

To see an example of this method used in a completed movie, see the Imaging movie in the Learning/Lingo folder inside the Director application folder.

Parameters

`x` Required if specifying a pixel using `x` and `y` coordinates. An integer that specifies the `x` coordinate of the pixel.

`y` Required if specifying a pixel using `x` and `y` coordinates. An integer that specifies the `y` coordinate of the pixel.

`point(x, y)` Required if specifying a pixel using a point. A point that specifies the pixel.
colorObjOrIntValue Required if setting the color to a color object or an integer value. A reference to a color object that specifies the color of the pixel, or an integer that specifies the color value of the pixel.

Example
This Lingo statement draws a horizontal black line 50 pixels from left to right in cast member 5:

See also
color(), draw(), fill(), getPixel(), image()

setPlayList()

Usage
-- Lingo syntax
soundChannelObjRef.setPlayList(linearListOfPropLists)

// JavaScript syntax
soundChannelObjRef.setPlayList(linearListOfPropLists);

Description
Sound Channel method; sets or resets the playlist of a sound channel.

This method is useful for queuing several sounds at once.

To see an example of setPlayList() used in a completed movie, see the Sound Control movie in the Learning/Lingo folder inside the Director application folder.

Parameters

<table>
<thead>
<tr>
<th>LinearListOfPropLists Required. A linear list of property lists that specifies parameters of a playlist. You can specify these parameters for each sound to be queued:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property</strong></td>
</tr>
<tr>
<td>#member</td>
</tr>
<tr>
<td>@startTime</td>
</tr>
<tr>
<td>@endTime</td>
</tr>
<tr>
<td>@loopCount</td>
</tr>
<tr>
<td>@loopStartTime</td>
</tr>
<tr>
<td>@loopEndTime</td>
</tr>
<tr>
<td>@preloadTime</td>
</tr>
</tbody>
</table>
**Example**

This handler queues and plays the cast member introMusic, starting at its 3-second point, with a loop repeated 5 times from the 8-second point to the 8.9-second point, and stopping at the 10-second point.

```-- Lingo syntax
on playMusic
    sound(2).queue([#member:member("introMusic"), #startTime:3000, #endTime:10000, #loopCount:5, #loopStartTime:8000, #loopEndTime:8900])
    sound(2).play()
end playMusic
// JavaScript syntax
function playMusic()
    sound(2).queue(propList("member",member("introMusic"), "startTime",3000, "endTime",10000, "loopCount",5, "loopStartTime",8000, "loopEndTime",8900));
    sound(2).play();
}
```

**See also**

endTime, getPlayerList(), loopCount, loopEndTime, loopStartTime, Member, member, preLoadTime, queue(), Sound Channel, startTime

### setPosition()

**Usage**

```-- Lingo syntax
_fileioObjRef.setPosition(intPosition)
// JavaScript syntax
_fileioObjRef.setPosition(intPosition);
```

**Description**

Fileio method; Sets the position of a file.

**Parameters**

*intPosition Required. An integer that specifies the new position of the file.

**See also**

Fileio

### setPref()

**Usage**

```-- Lingo syntax
_player.setPref(stringPrefName, prefString)
// JavaScript syntax
_player.setPref(stringPrefName, prefString);
```

**Description**

Player method; writes a specified string to a specified file on the computer's local disk. The file is a standard text file.
After `setPref()` runs, if the movie is playing in a browser, a folder named `Prefs` is created in the Plug-In Support folder. The `setPref()` method can write only to that folder.

If the movie is playing in a projector or Director, a folder is created in the same folder as the application. The folder receives the name `Prefs`.

Do not use this method to write to read-only media. Depending on the platform and version of the operating system, you may encounter errors or other problems.

In a browser, data written by `setPref()` is not private; any movie with Shockwave content can read this information and upload it to a server. Do not store confidential information using `setPref()`.

On Windows, `setPref()` fails if the user is a restricted user.

To see an example of `setPref()` used in a completed movie, see the Read and Write Text movie in the Learning/Lingo folder inside the Director application folder.

**Parameters**

- `prefName` Required. A string that specifies the file to write to. The `prefName` parameter must be a valid filename. To make sure the filename is valid on all platforms, use no more than eight alphanumeric characters for the file name.
- `prefValue` Required. A string that specifies the text to write to the file `prefName`.

**Example**

This handler saves the contents of the field cast member `Text Entry` in a file named `DayWare settings`:

```plaintext
-- Lingo syntax
on mouseUp me
    _player.setPref("CurPrefs", member("Text Entry").text)
end

// JavaScript syntax
function mouseUp() {
    _player.setPref("CurPrefs", member("Text Entry").text);
}
```

**See also**

`getPref()`, `Player`

**setProp**

**Usage**

```plaintext
setProp list, property, newValue
list[property] = newValue
```

**Description**

Command; in a list, replaces the value assigned to a specified property with a new value. If the list does not contain the specified property, `setProp` returns a script error.

The `setProp` command works with property lists only. Using `setProp` with a linear list produces a script error.
This command is similar to the `setaProp` command, except that `setProp` returns an error when the property is not already in the list.

**Parameters**

- **property** Required. A symbol (Lingo only) or a string that specifies the property whose value is replaced by `newValue`.
- **newValue** Required. The new value for the property specified by `property`.

**Example**

This statement changes the value assigned to the age property of property list x to 11:

```
setProp x, #age, 11
```

Using the dot operator, you can alter the property value of a property already in a list, exactly as above:

```
x.age = 11
```

**See also**

`setaProp`

**setScriptList()**

**Usage**

```lingo
spriteObjRef.setScriptList(scriptList)
sprite(whichSprite).setScriptList(scriptList)
```

**Description**

This command sets the `scriptList` of the given sprite. The `scriptList` indicates which scripts are attached to the sprite and what the settings of each script property are. By setting this list, you can change which behaviors are attached to a sprite or change the behavior properties.

The list takes the form:

```
[[ (whichBehaviorMember), "[ #property1: value, #property2: value, . . . ] "],
[(whichBehaviorMember), "[ #property1: value, #property2: value, . . . ] " ]]
```

This command cannot be used during a score recording session. Use `setScriptList()` for sprites added during score recording after the score recording session has ended.

**Parameters**

- **scriptList** Required. Specifies the script list for a given sprite.

**See also**

`scriptList`, `value()`, `string()`

**settingsPanel()**

**Usage**

```lingo
-- Lingo syntax
spriteObjRef.settingsPanel({integerPanelIndex})
```

```javascript
// JavaScript syntax
spriteObjRef.settingsPanel({integerPanelIndex});
```
**Description**

Flash sprite command; invokes the Flash Settings dialog box to the specified panel index. This is the same dialog box that can be opened by right-clicking (Windows) or Control-clicking (Macintosh) on a Flash movie playing in a browser.

The Settings dialog box will not be displayed if the Flash sprite’s rectangle is not large enough to accommodate it.

If you want to emulate the Flash Player by invoking the Settings dialog box when a user right-clicks (Windows) or Control-clicks (Macintosh), you can use this command in a `mouseDown` handler that tests for the `rightMouseDown` property or the `controlDown` property.

In order to emulate the Flash Player by enabling the Settings dialog box in a Director movie running in a browser, you must first disable the Shockwave Player context menu that is available by right-clicking (Windows) or Control-clicking (Macintosh) on a movie with Shockwave content playing in a browser. For information on how to disable this menu, see the Using Director topics in the Director Help Panel.

**Parameters**

- `integerPanelIndex` Optional. Specifies which panel to activate when the dialog box is opened.
  Valid values are 0, 1, 2, or 3. A value of 0 opens the dialog box showing the Privacy tab, a value of 1 opens it showing the Local Storage tab, a value of 2 opens it showing the Microphone tab, and a value of 3 opens it showing the Camera tab. The default panel index is 0.

**Example**

This statement opens the Flash Settings panel with the Local Storage tab active:

--- Lingo syntax
```lingo
sprite(3).settingsPanel(1)
```

// JavaScript syntax
```javascript
sprite(3).settingsPanel(1);
```

**See also**

- `on mouseDown (event handler)`, `rightMouseDown`, `controlDown`

**setPref()**

**Usage**

--- Lingo syntax
```lingo
_player.setPref(stringPrefName, prefString)
```

// JavaScript syntax
```javascript
_player.setPref(stringPrefName, prefString);
```

**Description**

Player method; writes the string specified by `prefString` in the file specified by `stringPrefName` on the computer’s local disk.

The `stringPrefName` argument must be a valid filename. To make sure the filename is valid on all platforms, use no more than eight alphanumeric characters for the file name.

After the `setPref()` method runs, if the movie is playing in a browser, a folder named Prefs is created in the Plug-In Support folder. The `setPref()` method can write only to that folder.
If the movie is playing in a projector or Director, a folder is created in the same folder as the application. The folder receives the name Prefs.

Do not use this method to write to read-only media. Depending on the platform and version of the operating system, you may encounter errors or other problems.

This method does not perform any sophisticated manipulation of the string data or its formatting. You must perform any formatting or other manipulation in conjunction with getPref(); you can manipulate the data in memory and write it over the old file using setPref().

In a browser, data written by setPref() is not private; any movie with Shockwave content can read this information and upload it to a server. Do not store confidential information using setPref().

On Windows, the setPref() method fails if the user is a restricted user.

To see an example of setPref() used in a completed movie, see the Read and Write Text movie in the Learning/Lingo folder inside the Director application folder.

Parameters

stringPrefName Required. A string that specifies the name of the file to which the string prefString is written. The file is a standard text file.

tPrefString Required. The string to write to the file specified by stringPrefName.

Example

This handler saves the contents of the field cast member Text Entry in a file named DayWare settings:

See also

getPref(), Player

setTrackEnabled()

Usage

-- Lingo syntax
spriteObjRef.setTrackEnabled(whichTrack, trueOrFalse)

// JavaScript syntax
spriteObjRef.setTrackEnabled(whichTrack, trueOrFalse);

Description

Command; determines whether the specified track in the digital video is enabled to play.

- When setTrackEnabled is TRUE, the specified track is enabled and playing.
- When setTrackEnabled is FALSE, the specified track is disabled and muted. For video tracks, this means they will no longer be updated on the screen.

To test whether a track is already enabled, test the trackEnabled sprite property.

Parameters

whichTrack Required. Specifies the track to test.
trueOrFalse Required. Specifies whether the track in the digital video is enabled (TRUE) or not (FALSE).

Example
This statement enables track 3 of the digital video assigned to sprite channel 8:

-- Lingo syntax
sprite(8).setTrackEnabled(3, TRUE)

// JavaScript syntax
sprite(8).setTrackEnabled(3, 1);

See also
trackEnabled

setVariable()

Usage

-- Lingo syntax
spriteObjRef.setVariable(variableName, newValue)

// JavaScript syntax
spriteObjRef.setVariable(variableName, newValue);

Description
Function; sets the value of the given variable in the given Flash sprite. Flash variables were introduced in Flash version 4.

Parameters

variableName Required. Specifies the name of the variable.

newValue Required. Specifies the new value of the variable.

Example
The following statement sets the value of the variable currentURL in the Flash cast member in sprite 3. The new value of currentURL will be “http://www.macromedia.com/software/flash/”.

-- Lingo syntax

// JavaScript syntax

hitTest(), getVariable()
shader()

Usage

member(whichCastmember).shader(whichShader)
member(whichCastmember).shader[index]
member(whichCastmember).model(whichModel).shader
member(whichCastmember).modelResource(whichModelResource).\
  face[index].shader

Description

3D element, model property, and face property; the object used to define the appearance of the surface of the model. The shader is the "skin" which is wrapped around the model resource used by the model.

The shader itself is not an image. The visible component of a shader is created with up to eight layers of texture. These eight texture layers are either created from bitmap cast members or image objects within Director or imported with models from 3D modeling programs. For more information, see texture.

Every model has a linear list of shaders called the shaderlist. The number of entries in this list equals the number of meshes in the model resource used by the model. Each mesh can be shaded by only one shader.

The 3D cast member has a default shader named DefaultShader, which cannot be deleted. This shader is used when no shader has been assigned to a model and when a shader being used by a model is deleted.

The syntax member(whichCastmember).model(whichModel).shader gives access to the first shader in the model's shaderlist and is equivalent to
member(whichCastmember).model(whichModel).shaderList[1].

Create and delete shaders with the newShader() and deleteShader() commands.

Shaders are stored in the shader palette of the 3D cast member. They can be referenced by name (whichShader) or palette index (shaderIndex). A shader can be used by any number of models.

Changes to a shader will appear in all models which use that shader.

There are four types of shaders:

#standard shaders present their textures realistically.
#painter, #engraver, and #newsprint shaders stylize their textures for painting, engraving, and newsprint effects. They have special properties in addition to the #standard shader properties.

The shaders used by individual faces of #mesh primitives can be set with the syntax
member(whichCastmember).modelResource(whichModelResource).face[index].shader.

Changes to this property require a call to the build() command.

Example

This statement sets the shader property of the model named Wall to the shader named WallSurface:

member("Room").model("Wall").shader = \n  member("Room").shader("WallSurface")

See also

shaderList, newShader, deleteShader, face[ ], texture()
showLocals()

Usage
-- Lingo syntax
showLocals()

Description
Top level function (Lingo only); displays all local variables in the Message window. This command is useful only within handlers or parent scripts that contain local variables to display. All variables used in the Message window are automatically global.

Local variables in a handler are no longer available after the handler executes. Inserting the statement `showLocals()` in a handler displays all the local variables in that handler in the Message window.

This command is useful for debugging scripts.

Parameters
None.

See also
clearGlobals(), global, showGlobals()

showProps()

Usage
-- Lingo syntax
memberOrSpriteObjRef.showProps()

// JavaScript syntax
memberOrSpriteObjRef.showProps();

Description
Command; displays a list of the current property settings of a Flash movie, Vector member, or currently playing sound in the Message window. This command is useful for authoring only; it does not work in projectors or in movies with Shockwave content.

Parameters
None.

Example
This handler accepts the name of a cast as a parameter, searches that cast for Flash movie cast members, and displays the cast member name, number, and properties in the Message window:

-- Lingo syntax
on ShowCastProperties(whichCast)
    repeat with i = 1 to castLib(whichCast).member.count
        castType = member(i, whichCast).type
        if (castType = #flash) OR (castType = #vectorShape) then
            put castType&&"cast member" && i & ":" && member(i, whichCast).name
            put RETURN
        member(i, whichCast).showProps()
    end if
end repeat
showGlobals()

Usage

-- Lingo syntax
_global.showGlobals()

// JavaScript syntax
_global.showGlobals();

Parameters

None.

Description

Global method; displays all global variables in the Message window.
This method is useful for debugging scripts.

Example

This statement displays all global variables in the Message window:

-- Lingo syntax
on mouseDown
    _global.showGlobals()
end

// JavaScript syntax
function mouseDown()
    _global.showGlobals();
}

See also

Global
shutDown()

Usage

-- Lingo syntax
_system.shutDown()

// JavaScript syntax
_system.shutDown();

Description

System method; closes all open applications and turns off the computer.

Parameters

None.

Example

This statement checks whether the user has pressed Control+S (Windows) or Command+S (Macintosh) and, if so, shuts down the computer:

See also

System

sin()

Usage

sin(angle)

Description

Math function (Lingo only); calculates the sine of the specified angle. The angle must be expressed in radians as a floating-point number.

In JavaScript syntax, use the Math object’s sin() function.

Parameters

angle Required. Specifies the angle.

Example

This statement calculates the sine of π/2:

put sin (PI/2.0)
-- 1

See also

PI
sort

Usage

list.sort()
sort list

Description
Command; puts list items into alphanumeric order.

- When the list is a linear list, the list is sorted by values.
- When the list is a property list, the list is sorted alphabetically by properties.

After a list is sorted, it maintains its sort order even when you add new variables using the add command.

Parameters

None.

Example

The following statement puts the list Values, which consists of [#a: 1, #d: 2, #c: 3], into alphanumeric order. The result appears below the statement.

put values
-- [#a: 1, #d: 2, #c: 3]
values.sort()
put values
-- [#a: 1, #c: 3, #d: 2]

sound()

Usage

-- Lingo syntax
sound(intSoundChannel)

// JavaScript syntax
sound(intSoundChannel);

Description

Top level function; returns a reference to a specified sound channel.

The functionality of this method is identical to the Sound object's channel() method.

Parameters

intSoundChannel Required. An integer that specifies the sound channel to reference.

Example

The following example assigns sound channel 1 to a variable music and plays a sound.

-- Lingo syntax
music = sound(1)
music.play(member("waltz1"))

// JavaScript syntax
var music = sound(1);
music.play(member("waltz1"));
See also
channel() (Sound), Sound Channel

sprite()

Usage

-- Lingo syntax
sprite(nameOrNum)

// JavaScript syntax
sprite(nameOrNum);

Description
Top level function; returns a reference to a given sprite in the Score.
If the Score does not contain the given sprite, this function returns an empty string.

Parameters

nameOrNum Required. A string or integer that specifies the name or index position of the sprite.

Example
This statement sets the variable thisSprite to the sprite named Cave:

-- Lingo syntax
thisSprite = sprite("Cave")

// JavaScript syntax
var thisSprite = sprite("Cave");

See also
Sprite Channel

spriteSpaceToWorldSpace

Usage

sprite(whichSprite).camera.spriteSpaceToWorldSpace(loc)
sprite(whichSprite).camera(index).spriteSpaceToWorldSpace(loc)

Description
3D command; returns a world-space position that is found on the specified camera's projection plane that corresponds to a location within the referenced sprite.
The projection plane is defined by the camera's X and Y axes, and is at a distance in front of the camera such that one pixel represents one world unit of measurement. It is this projection plane that is used for the sprite display on stage.
The camera.spriteSpaceToWorldSpace() form of this command is a shortcut for using camera(1).spriteSpaceToWorldSpace().
All cameras that are used by the referenced sprite will respond to the spriteSpaceToWorldSpace command as if their display rect is the same size as the sprite.
Parameters

loc Required. Specifies the location in the referenced sprite. This location should be a point relative to the sprite’s upper-left corner.

Example

This statement shows that the point (50, 50) within sprite 5 is equivalent to the vector (-1993.6699, 52.0773, 2263.7446) on the projection plane of the camera of sprite 5:

```lingo
put sprite(5).camera.spriteSpaceToWorldSpace(point(50, 50))
-- vector(-1993.6699, 52.0773, 2263.7446)
```

See also

`worldSpaceToSpriteSpace, rect (camera), camera`

sqrt()

Usage

```lingo
sqrt(number)
```

the sqrt of number

Description

Math function (Lingo only); returns the square root of a specified number.

The value must be a decimal number greater than 0. Negative values return 0.

In JavaScript syntax, use the Math object’s `sqrt()` function.

Parameters

number Required. Specifies the number. This number is either a floating-point number or an integer rounded to the nearest integer.

Example

This statement displays the square root of 3.0 in the Message window:

```lingo
put sqrt(3.0)
-- 1.7321
```

This statement displays the square root of 3 in the Message window:

```lingo
put sqrt(3)
-- 2
```

See also

`floatPrecision`
**stageBottom**

**Usage**
the stageBottom

**Description**
Function; along with stageLeft, stageRight, and stageTop, indicates where the Stage is positioned on the desktop. It returns the bottom vertical coordinate of the Stage relative to the upper left corner of the main screen. The height of the Stage in pixels is determined by the stageBottom - the stageTop.

When the movie plays back as an applet, the stageBottom property is the height of the applet in pixels.

This function can be tested but not set.

**Parameters**
None.

**Example**
These statements position sprite 3 a distance of 50 pixels from the bottom edge of the Stage:

```director
stageHeight = the stageBottom - the stageTop
sprite(3).locV = stageHeight - 50
```

Sprite coordinates are expressed relative to the upper left corner of the Stage. For more information, see the Using Director topics in the Director Help Panel.

**See also**
stageLeft, stageRight, stageTop, locH, locV

---

**stageLeft**

**Usage**
the stageLeft

**Description**
Function; along with stageRight, stageTop, and stageBottom, indicates where the Stage is positioned on the desktop. It returns the left horizontal coordinate of the Stage relative to the upper left corner of the main screen. When the Stage is flush with the left side of the main screen, this coordinate is 0.

When the movie plays back as an applet, the stageLeft property is 0, which is the location of the left side of the applet.

This property can be tested but not set.

Sprite coordinates are expressed relative to the upper left corner of the Stage.

**Parameters**
None.
Example

This statement checks whether the left edge of the Stage is beyond the left edge of the screen and calls the handler `leftMonitorProcedure` if it is:

```lingo
if the stageLeft < 0 then leftMonitorProcedure
```

See also

`stageBottom, stageRight, stageTop, locH, locV`

stageRight

Usage

```lingo
the stageRight
```

Description

Function; along with `stageLeft, stageTop, and stageBottom`, indicates where the Stage is positioned on the desktop. It returns the right horizontal coordinate of the Stage relative to the upper left corner of the main screen's desktop. The width of the Stage in pixels is determined by the `stageRight - the stageLeft`.

When the movie plays back as an applet, the `stageRight` property is the width of the applet in pixels.

This function can be tested but not set.

Sprite coordinates are expressed relative to the upper left corner of the Stage.

Parameters

None.

Example

These two statements position sprite 3 a distance of 50 pixels from the right edge of the Stage:

```lingo
stageWidth = the stageRight - the stageLeft
sprite(3).locH = stageWidth - 50
```

See also

`stageLeft, stageBottom, stageTop, locH, locV`

stageToFlash()

Usage

```lingo
-- Lingo syntax
spriteObjRef.stageToFlash(pointOnDirectorStage)
```

```javascript
// JavaScript syntax
spriteObjRef.stageToFlash(pointOnDirectorStage);
```

Description

Function; returns the coordinate in a Flash movie sprite that corresponds to a specified coordinate on the Director Stage. The function both accepts the Director Stage coordinate and returns the Flash movie coordinate as Director point values: for example, point (300,300).
Flash movie coordinates are measured in Flash movie pixels, which are determined by the original size of the movie when it was created in Flash. Point (0,0) of a Flash movie is always at its upper left corner. (The cast member's originPoint property is not used to calculate movie coordinates; it is used only for rotation and scaling.)

The stageToFlash() function and the corresponding flashToStage() function are helpful for determining which Flash movie coordinate is directly over a Director Stage coordinate. For both Flash and Director, point (0,0) is the upper left corner of the Flash Stage or Director Stage. These coordinates may not match on the Director Stage if a Flash sprite is stretched, scaled, or rotated.

Parameters

pointOnDirectorStage Required. Specifies the point on the Director stage.

Example

The following handler checks to see if the mouse pointer (whose location is tracked in Director Stage coordinates) is over a specific coordinate (130,10) in a Flash movie sprite in channel 5. If the pointer is over that Flash movie coordinate, the script stops the Flash movie.

-- Lingo syntax
on checkFlashRollover
  if sprite(5).stageToFlash(point(_mouse.mouseH,_mouse.mouseV)) = point(130,10) then
    sprite(5).stop()
  end if
end

// JavaScript syntax
function checkFlashRollover() {
  var stf = sprite(5).stageToFlash(point(_mouse.mouseH,_mouse.mouseV));
  if (stf = point(130,10)) {
    sprite(5).stop();
  }
}

See also

flashToStage()

stageTop

Usage

the stageTop

Description

Function: along with stageBottom, stageLeft, and stageRight, indicates where the Stage is positioned on the desktop. It returns the top vertical coordinate of the Stage relative to the upper left corner of the main screen's desktop. If the Stage is in the upper left corner of the main screen, this coordinate is 0.

When the movie plays back as an applet, the stageTop property is always 0, which is the location of the left side of the applet.

This function can be tested but not set.

Sprite coordinates are expressed relative to the upper left corner of the Stage.

---
Parameters
None.

Example
This statement checks whether the top of the Stage is beyond the top of the screen and calls the handler upperMonitorProcedure if it is:
if the stageTop < 0 then upperMonitorProcedure

See also
stageLeft, stageRight, stageBottom, locH, locV

status()

Usage
-- Lingo syntax
dfileioObjRef.status()

// JavaScript syntax
dfileioObjRef.status();

Description
Fileio method; Returns the error code of the last method called.

Parameters
None.

See also
Fileio

stop() (DVD)

Usage
-- Lingo syntax
dvdObjRef.stop()

// JavaScript syntax
dvdObjRef.stop();

Description
DVD method; stops playback.
This method returns TRUE (1) if successful.

Parameters
None.

See also
DVD
stop() (Sound Channel)

Usage
-- Lingo syntax
soundChannelObjRef.stop()

// JavaScript syntax
soundChannelObjRef.stop();

Description
Sound Channel method; stops the currently playing sound in a sound channel.
Issuing a play() method begins playing the first sound of those that remain in the queue of the given sound channel.
To see an example of stop() used in a completed movie, see the Sound Control movie in the Learning/Lingo folder inside the Director application folder.

Parameters
None.

Example
This statement stops playback of the sound cast member currently playing in sound channel 1:
-- Lingo syntax
sound(1).stop()

// JavaScript syntax
sound(1).stop();

See also
getPlayList(), pause() (Sound Channel), play() (Sound Channel), playNext() (Sound Channel), rewind() (Sound Channel), Sound Channel

stop() (Flash)

Usage
-- Lingo syntax
spriteObjRef.stop()

// JavaScript syntax
spriteObjRef.stop();

Description
Flash command; stops a Flash movie sprite that is playing in the current frame.

Parameters
None.
Example

This frame script stops the Flash movie sprites playing in channels 5 through 10:

```lingo
-- Lingo syntax
on enterFrame
    repeat with i = 5 to 10
        sprite(i).stop()
    end repeat
end
```

```
// JavaScript syntax
function enterFrame() {
    var i = 5;
    while (i < 11) {
        sprite(i).stop();
        i++;
    }
}
```

See also

hold()

stop() (RealMedia, SWA, Windows Media)

Usage

```lingo
-- Lingo syntax
windowsMediaObjRef.stop()
realMediaObjRef.stop()
```

```
// JavaScript syntax
windowsMediaObjRef.stop();
realMediaObjRef.stop();
```

Description

Windows Media or RealMedia cast member or sprite method. Stops playback of a Windows Media or RealMedia cast member or sprite.

Parameters

None.

Example

The following examples stop sprite 2 and the cast member Real from playing:

```lingo
-- Lingo syntax
sprite(2).stop()
member("Real").stop()
```

```
// JavaScript syntax
sprite(2).stop();
member("Real").stop();
```

See also

RealMedia, Windows Media
stopEvent()

Usage

-- Lingo syntax
_movie.stopEvent()

// JavaScript syntax
_movie.stopEvent();

Description

Movie method; prevents scripts from passing an event message to subsequent locations in the message hierarchy.

This method also applies to sprite scripts.

Use the stopEvent() method to stop the message in a primary event handler or a sprite script, thus making the message unavailable for subsequent sprite scripts.

By default, messages are available first to a primary event handler (if one exists) and then to any scripts attached to a sprite involved in the event. If more than one script is attached to the sprite, the message is available to each of the sprite's scripts. If no sprite script responds to the message, the message passes to a cast member script, frame script, and movie script, in that order.

The stopEvent() method applies only to the current event being handled. It does not affect future events. The stopEvent() method applies only within primary event handlers, handlers that primary event handlers call, or multiple sprite scripts. It has no effect elsewhere.

Parameters

None.

Example

This statement shows the mouseUp event being stopped in a behavior if the global variable grandTotal is equal to 500:

-- Lingo syntax
global grandTotal

on mouseUp me
  if (grandTotal = 500) then
    _movie.stopEvent()
  end if
end

// JavaScript syntax
_global.grandTotal;

function mouseUp() {
  if (_global.grandTotal == 500) {
    _movie.stopEvent();
  }
}

Neither subsequent scripts nor other behaviors on the sprite receive the event if it is stopped in this manner.

See also

Movie
stream()

Usage

-- Lingo syntax
memberObjRef.stream(numberOfBytes)

// JavaScript syntax
memberObjRef.stream(numberOfBytes);

Description

Command; manually streams a portion of a specified Flash movie cast member into memory.

The \textit{stream} command returns the number of bytes actually streamed. Depending on a variety of conditions (such as network speed or the availability of the requested data), the number of bytes actually streamed may be less than the number of bytes requested.

You can always use the \textit{stream} command for a cast member regardless of the cast member's \textit{streamMode} property.

Parameters

\texttt{numberOfBytes} Optional. An integer that specifies the number of bytes to stream. If you omit the \texttt{numberOfBytes} parameter, Director tries to stream the number of bytes set by the cast member's \texttt{bufferSize} property.

Example

The following frame script checks to see if a linked Flash movie cast member has streamed into memory by checking its \texttt{percentStreamed} property. If the cast member is not completely loaded into memory, the script tries to stream 32,000 bytes of the movie into memory.

The script also saves the actual number of bytes streamed in a variable called \texttt{bytesReceived}. If the number of bytes actually streamed does not match the number of bytes requested, the script updates a text cast member to report the number of bytes actually received. The script keeps the playhead looping in the current frame until the cast member has finished loading into memory.

-- Lingo syntax
on exitFrame
  if member(10).percentStreamed < 100 then
    bytesReceived = member(10).stream(32000)
    if bytesReceived < 32000 then
      member("Message Line").text = "Received only" && bytesReceived " of 32,000 bytes requested."
      _movie.updateStage()
    else
      member("Message Line").text = "Received all 32,000 bytes."
    end if
  end if
  _movie.go(_movie.frame)
end

// JavaScript syntax
function exitFrame()
  var pctStm = member(10).percentStreamed;
  if (pctStm < 100) {
    var bytesReceived = member(10).stream(32000);
    if (bytesReceived < 32000) {
      member("Message Line").text = "Received only" && bytesReceived " of 32,000 bytes requested."
      _movie.updateStage()
    } else
      member("Message Line").text = "Received all 32,000 bytes."
  } else
    _movie.go(_movie.frame)
  end if
end

stream() 551
member("Message Line").text = "Received only " + bytesReceived + " of 32,000 bytes requested."
_movie.updateStage();
} else {
    member("Message Line").text = "Received all 32,000 bytes."
}
_movie.go(_movie.frame);
}

string()

Usage
string(expression)

Description
Function; converts an integer, floating-point number, object reference, list, symbol, or other nonstring expression to a string.

Parameters
expression Required. The expression to convert to a string.

Example
This statement adds 2.0 + 2.5 and inserts the results in the field cast member Total:
member("total").text = string(2.0 + 2.5)
This statement converts the symbol #red to a string and inserts it in the field cast member Color:
member("Color").text = string(#red)

See also
value(), stringP(), float(), integer(), symbol()

stringP()

Usage
stringP(expression)

Description
Function; determines whether an expression is a string (TRUE) or not (FALSE).
The P in stringP stands for predicate.

Parameters
expression Required. The expression to test.

Example
This statement checks whether 3 is a string:
put stringP("3")
The result is 1, which is the numeric equivalent of TRUE.
This statement checks whether the floating-point number 3.0 is a string:

```
put stringP(3.0)
```

Because 3.0 is a floating-point number and not a string, the result is 0, which is the numeric equivalent of `FALSE`.

`floatP(), ilk(), integerP(), objectP(), symbolP()`

### subPictureType()

**Usage**

**-- Lingo syntax**

```
dvdObjRef.subPictureType(intStream)
```

**// JavaScript syntax**

```
dvdObjRef.subPictureType(intStream);
```

**Description**

DVD method; specifies the type of a specified sub-picture stream.

This method can return the following values:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#unknown</td>
<td>The sub-picture type is unknown.</td>
</tr>
<tr>
<td>#Language</td>
<td>The sub-picture contains language-related content such as movie subtitles or other text.</td>
</tr>
<tr>
<td>#Other</td>
<td>The sub-picture contains non language-related content such as a bouncing ball in karaoke titles.</td>
</tr>
</tbody>
</table>

**Parameters**

`intStream` Required. An integer that specifies the stream to test.

**Example**

This statement returns the sub-picture type in stream 2:

```
-- Lingo syntax
sprite(12).member.subPictureType(2)

// JavaScript syntax
sprite(12).member.subPictureType(2);
```

**See also**

`DVD`
substituteFont

Usage

TextMemberRef.substituteFont(originalFont, newFont)
substituteFont(textMemberRef, originalFont, newFont)

Description

Text cast member command; replaces all instances of one font with another font in a text cast member.

Parameters

originalFont Required. The font to replace.
newFont Required. The new font that replaces the font specified by originalFont.

Example

This script checks to see if the font Bonneville is available in a text cast member, and replaces it with Arial if it is not:

-- Lingo syntax
property spriteNum

on beginSprite me
    currMember = sprite(spriteNum).member
    if currMember.missingFonts contains "Bonneville" then
        currMember.substituteFont("Bonneville", "Arial")
    end if
end

// JavaScript syntax
function beginSprite() {
    currMember = sprite(spriteNum).member;
    if (currMember.missingFonts contains "Bonneville") { //check syntax
        currMember.substituteFont("Bonneville", "Arial");
    }
}

See also

missingFonts

swing()

Usage

-- Lingo syntax
spriteObjRef.swing(pan, tilt, fieldOfView, speedToSwing)

// JavaScript syntax
spriteObjRef.swing(pan, tilt, fieldOfView, speedToSwing);

Description

QuickTime VR sprite function; swings a QuickTime 3 sprite containing a VR Pano around to the new view settings. The swing is a smooth “camera dolly” effect.

whichQTvsSprite is the sprite number of the sprite with the QuickTime VR member.
The function returns immediately, but the sprite continues to change view until it reaches the final view. The duration required to change to the final settings varies depending on machine type, size of the sprite rectangle, color depth of the screen, and other typical performance constraints.

To check if the swing has finished, check if the *pan* property of the sprite has arrived at the final value.

**Parameters**

*pan* Required. Specifies the new pan position, in degrees.

*tilt* Required. Specifies the new tilt, in degrees.

*fieldOfView* Required. Specifies the new field of view, in degrees.

*speedToSwing* Required. Specifies the rate at which the swing should take place. Valid values range from 1 (slow) to 10 (fast).

**Example**

This very gradually adjusts the view of QTVR sprite 1 to a pan position of 300°, a tilt of -15°, and a field of view of 40°:

```-- Lingo syntax
sprite(1).swing(300, -15, 40, 1)
// JavaScript syntax
sprite(1).swing(300, -15, 40, 1);
```

**See also**

*pan (QTVR property)*

---

**symbol()**

**Usage**

```-- Lingo syntax
symbol(stringValue)
// JavaScript syntax
symbol(stringValue);
```

**Description**

Top level function; takes a string and returns a symbol.

**Parameters**

*stringValue* Required. The string to convert to a symbol.

**Example**

This statement displays the symbol #hello:

```-- Lingo syntax
put(symbol("hello"))
// JavaScript syntax
put(symbol("hello"));
```
This statement displays the symbol #goodbye:

```
--Lingo syntax
x = "goodbye"
put(symbol(x))

// JavaScript syntax
var x = "goodbye";
put(symbol(x));
```

See also

`value()`, `string()`

### symbolP()

**Usage**

```
Expression.symbolP
symbolP(expression)
```

**Description**

Function; determines whether a specified expression is a symbol (`TRUE`) or not (`FALSE`). The `P` in `symbolP` stands for predicate.

**Parameters**

- `expression` Required. Specifies the expression to test.

**Example**

This statement checks whether the variable `myVariable` is a symbol:

```
put myVariable.symbolP
```

See also

`ilk()`

### tan()

**Usage**

```
tan(angle)
```

**Description**

Math function; yields the tangent of the specified angle expressed in radians as a floating-point number.

In JavaScript syntax, use the Math object's `tan()` function.

**Parameters**

- `angle` Required. Specifies the angle from which a tangent is yielded.

**Example**

The following function yields the tangent of pi/4:

```
tan (PI/4.0) = 1
```

The π symbol cannot be used in a Lingo expression.
tellStreamStatus()

Usage

tellStreamStatus(onOrOffBoolean)

Description

Function; turns the stream status handler on (TRUE) or off (FALSE).

The form `tellStreamStatus()` determines the status of the handler.

When the `streamStatusHandler` is TRUE, Internet streaming activity causes periodic calls to the movie script, triggering `streamStatusHandler`. The handler is executed, with Director automatically filling in the parameters with information regarding the progress of the downloads.

Parameters

`onOrOffBoolean` Optional. Specifies the status of the handler.

Example

This on prepareMovie handler turns the on streamStatus handler on when the movie starts:

```-- Lingo syntax
on prepareMovie
  tellStreamStatus(TRUE)
end

// JavaScript syntax
function prepareMovie() {
  tellStreamStatus(TRUE);
}
```

This statement determines the status of the stream status handler:

```-- Lingo syntax
on mouseDown
  put tellStreamStatus()
end

// JavaScript syntax
function mouseDown() {
  put(tellStreamStatus());
}
```

See also

`on streamStatus`
tellTarget()

Usage

-- Lingo syntax
spriteObjRef.tellTarget(targetName)

// JavaScript syntax
spriteObjRef.tellTarget(targetName);

Description

Command; equivalent to the Flash beginTellTarget and endTellTarget methods. The tellTarget() command allows the user to set a target Timeline on which subsequent sprite commands will act. When the target is set to a Flash movie clip or a level containing a loaded Flash movie, certain commands act on the targeted components, rather than on the main Timeline. To switch focus back to the main Timeline, call endTellTarget().

The only valid argument for tellTarget is the target name. There is no valid argument for endTellTarget.

The Flash sprite functions that are affected by tellTarget are stop, play, getProperty, setProperty, gotoFrame, call(frame), and find(label). In addition, the sprite property frame (which returns the current frame) is affected by tellTarget.

Parameters

targetName Required. Specifies the target name.

Example

This command sets the movie clip as the target:

-- Lingo syntax
sprite(1).tellTarget("\myMovieClip")

// JavaScript syntax
sprite(1).tellTarget("\myMovieClip");

This command stops the movie clip:

-- Lingo syntax
sprite(1).stop()

// JavaScript syntax
sprite(1).stop();

This command causes the movie clip to play:

-- Lingo syntax
sprite(1).play()

// JavaScript syntax
sprite(1).play();

This command switches the focus back to the main Timeline:

-- Lingo syntax
sprite(1).endTellTarget()

// JavaScript syntax
sprite(1).endTellTarget();
This command stops the main movie:

```
-- Lingo syntax
sprite(1).stop()

// JavaScript syntax
sprite(1).stop();
```

texture()

Usage

```
member(whichCastmember).texture(whichTexture)
member(whichCastmember).texture[index]
member(whichCastmember).shader(whichShader).texture
member(whichCastmember).model(whichModel).shader.texture
member(whichCastmember).model(whichModel).shaderList.texture
member(whichCastmember).model(whichModel).shaderList[index].texture
member(whichCastmember).modelResource(whichParticleSystemModel\Resource).texture
```

Description

3D element and shader property; an image object used by a shader to define the appearance of the surface of a model. The image is wrapped onto the geometry of the model by the shader.

The visible component of a shader is created with up to eight layers of textures. These eight texture layers are either created from bitmap cast members or image objects within Director or imported with models from 3D modeling programs.

Create and delete textures with the `newTexture()` and `deleteTexture()` commands.

Textures are stored in the texture palette of the 3D cast member. They can be referenced by name (`whichTexture`) or palette index (`textureIndex`). A texture can be used by any number of shaders. Changes to a texture will appear in all shaders which use that texture.

There are three types of textures:

- `#fromCastmember`; the texture is created from a bitmap cast member using the `newTexture()` command.
- `#fromImageObject`; the texture is created from a lingo image object using the `newTexture()` command.
- `#importedFromFile`; the texture is imported with a model from a 3D modeling program.

The texture of a particle system is a property of the model resource, whose type is `#particle`.

Example

This statement sets the `texture` property of the shader named `WallSurface` to the texture named BluePaint:

```
member("Room").shader("WallSurface").texture = \
member("Room").texture("BluePaint")
```

See also

`newTexture, deleteTexture`
time() (System)

Usage
-- Lingo syntax
_system.time()

// JavaScript syntax
_system.time();

Description
System method; returns the current time in the system clock as a string.
The returned time is formatted as follows:
1:30 PM

Parameters
None.

Example
The following handler outputs the current time to a text field.

-- Lingo syntax
on exitFrame
   member("clock").text = _system.time()
end

// JavaScript syntax
function exitFrame() {
   member("clock").text = _system.time();
}

See also
date() (System). System

timeout()

Usage
-- Lingo syntax
timeout(timeoutObjName)

// JavaScript syntax
timeout(timeoutObjName);

Description
Top level function; returns a given timeout object.
Use the new() method to create a new timeout object and add it to the timeoutList.

Parameters
timeoutObjName Required. A string that specifies the name of the timeout object to return.
Example

This handler deletes the timeout object named Random Lightning:

-- Lingo syntax
on exitFrame
    timeout("Random Lightning").forget()
end

// JavaScript syntax
function exitFrame() {
    timeout("Random Lightning").forget();
}

See also

new(), timeoutList

titleMenu()

Usage

-- Lingo syntax
dvdObjRef.titleMenu()

// JavaScript syntax
dvdObjRef.titleMenu();

Description

DVD method; displays the title menu.

Parameters

None.

See also

DVD

top (3D)

Usage

modelResourceObjectReference.top

Description

3D command; when used with a model resource whose type is #box, allows you to both get and set the top property of the model resource.

The top property determines whether the top of the box is sealed (TRUE) or open (FALSE). The default value is TRUE.

Parameters

None.
Example
This statement sets the top property of the model resource Gift box to FALSE, meaning the top of this box will be open:

```
member("3D World").modelResource("Gift box").top = FALSE
```

See also
back, bottom (3D), front

topCap

Usage
```
modelResourceObjectReference.topCap
```

Description
3D command; when used with a model resource whose type is #cylinder, allows you to both get and set the topCap property of the model resource.

The topCap property determines whether the top cap of the cylinder is sealed (TRUE) or open (FALSE). The default value for this property is FALSE.

Parameters
None.

Example
This statement sets the topCap property of the model resource Tube to FALSE, meaning the top of this cylinder will be open:

```
member("3D World").modelResource("Tube").topCap = FALSE
```

topRadius

Usage
```
modelResourceObjectReference.topRadius
```

Description
3D command; when used with a model resource whose type is #cylinder, allows you to both get and set the topRadius property of the model resource, as a floating-point value.

The topRadius property determines the radius of the top cap of the cylinder. This property must always be 0.0 or greater. The default value is 25.0. Setting topRadius to 0.0 produces a cone.

Parameters
None.

Example
The following statement sets the topRadius property of the model resource Tube to 0.0. If the bottom radius has a value greater than 0, models using Tube will be conical.

```
member("3D World").modelResource("Tube").topRadius = 0.0
```
### trace()

**Usage**

**Lingo syntax**
```
trace(value)
```

**JavaScript syntax**
```
trace(value);
```

**Description**

Top level function; evaluates an expression and displays the result in the Message window.

The functionality of this method is identical to the top level `put()` method, which is also available to both Lingo and JavaScript syntax.

This method can be used as a debugging tool by tracking the values of variables as a movie plays.

**Parameters**

- `value` Required. The expression to evaluate.

**Example**

The following statement outputs the value of the variable `counter` to the Message window.

**Lingo syntax**
```
counter = (_system.milliseconds / 1000)
trace(counter)
```

**JavaScript syntax**
```
var counter = (_system.milliseconds / 1000);
trace(counter);
```

**See also**

`put()`

---

### transform (command)

**Usage**

transform()
transform(n1, n2, n3, ..., n14, n15, n16)

**Description**

3D command; this command creates a transform object. When this command is used without providing any parameters it creates a transform object equal to the identity transform. The identity transform has positional and rotational components of vector(0,0,0), and it has a scale component of vector(1,1,1). When this command is used while providing sixteen parameters in the form of `n1, n2, n3, ..., n14, n15, n16` then this command creates a transform object using those 16 entries for the transform data.

**Parameters**

- `n1, n2, n3, ..., n14, n15, n16` Optional. Specifies the sixteen parameters that are used as the transform data when creating the transform object.
Example

This statement creates an identity transform and stores it in the variable `tTransform`:

```python
tTransform = transform()
```

This statement creates an identity transform by specifying all 16 of its elements, and it stores the new transform in the variable `tTransform`.

```python
tTransform = transform(1.0000, 0.0000, 0.0000, 0.0000, \\
                    0.0000, 1.0000, 0.0000, 0.0000, \\
                    0.0000, 0.0000, 1.0000, 0.0000, \\
                    0.0000, 0.0000, 0.0000, 1.0000)
```

This statement creates a custom transform by specifying all 16 of its elements, and it stores the new transform in the variable `tTransform`. The transform created has a **position** property of `vector(19.2884, 1.7649, 4.2426)`, a **rotation** property of `vector(75.7007, 0.0000, -6.5847)` and a **scale** property of `vector(0.4904, 0.7297, 0.3493)`.

```python
tTransform = transform(0.4872, -0.0562, 0.0000, 0.0000, \\
                    0.0795, 0.1722, 0.7071, 0.0000, \\
                    -0.0795, -0.1722, 0.7071, 0.0000, \\
                    19.2884, 1.7649, 4.2426, 1.0000)
```

See also

- `transform (property)`, `preRotate`, `preTranslate()`, `preScale()`, `rotate`, `translate`, `scale (command)`

### translate

Usage

```python
member(whichCastmember).node(whichNode).translate(xIncrement, \\
yIncrement, zIncrement \{, relativeTo\})

member(whichCastmember).node(whichNode).translate\(\)
  (translateVector \{, relativeTo\})

transform.translate(xIncrement, yIncrement, zIncrement \{
  , relativeTo\})

transform.translate(translateVector \{, relativeTo\})
```

Description

3D command; applies a translation after the current positional, rotational, and scale offsets held by a referenced node or the directly referenced transform object. The translation must be specified as a set of three increments along the three corresponding axes. These increments may be specified explicitly in the form of `xIncrement`, `yIncrement`, and `zIncrement`, or by a `translateVector`, where the x component of the vector corresponds to the translation along the x axis, y about y axis, and z about z axis.

A node can be a camera, model, light or group object.

Parameters

- **xIncrement** Required if specifying a set of three increments. Specifies the x-axis increment.
- **yIncrement** Required if specifying a set of three increments. Specifies the y-axis increment.
- **zIncrement** Required if specifying a set of three increments. Specifies the z-axis increment.
- **translateVector** Required if specifying a vector. Specifies the vector that contains the x, y, and z components.
**relativeTo** Optional. Determines which coordinate system's axes are used to apply the desired translational changes. The `relativeTo` parameter can have any of the following values:

- **#self** applies the increments relative to the node's local coordinate system (the x, y and z axes specified for the model during authoring). This value is used as the default if you use the `translate` command with a node reference and the `relativeTo` parameter is not specified.
- **#parent** applies the increments relative to the node's parent's coordinate system. This value is used as the default if you use the `translate` command with a transform reference and the `relativeTo` parameter is not specified.
- **#world** applies the increments relative to the world coordinate system. If a model's parent is the world, than this is equivalent to using `#parent`.
- **nodeReference** allows you to specify a node to base your translation upon, the command applies the translations relative to the coordinate system of the specified node.

**Example**

This example constructs a transform using the transform command, then it initializes the transform's position and orientation in space before assigning the transform to the model named mars. Finally this example displays the resulting position of the model.

```lingo
t = transform()
t.transform.identity()
t.transform.rotate(0, 90, 0)
t.transform.translate(100, 0, 0)
gbModel = member("scene").model("mars")
gbModel.transform = t
put gbModel.transform.position
-- vector(100.0000, 0.0000, 0.0000)
```

This Lingo moves the model Bip 20 units along the x axis of its parent node:

```lingo
put member("Scene").model("Bip").position
-- vector(-38.5000, 21.2500, 2.0000)
member("Scene").model("Bip").translate(20, 10, -0.5)
put member("Scene").model("Bip").position
-- vector(-18.5000, 31.2500, 1.5000)
```

See also

- `transform` (property), `preTranslate()`, `scale` (command), `rotate`

---

**union()**

**Usage**

```lingo
rect(1).union(rect(2))
union (rect1, rect2)
```

**Description**

Function; returns the smallest rectangle that encloses two rectangles.

**Parameters**

- `rect2` Required. Specifies the second rectangle.
Example
This statement returns the rectangle that encloses the specified rectangles:

```lingo
put union (rect (0, 0, 10, 10), rect (15, 15, 20, 20))
-- rect (0, 0, 20, 20)
```
or

```lingo
put rect(0, 0, 10, 10).union(rect(15, 15, 20, 20))
--rect (0, 0, 20, 20)
```

See also
map(), rect()

unLoad() (Member)

Usage
```
-- Lingo syntax
memberObjRef.unLoad({|toMemberObjRef|})

// JavaScript syntax
memberObjRef.unLoad({|toMemberObjRef|});
```

Description
Member method; forces Director to clear the specified cast members from memory.
Director automatically unloads the least recently used cast members to accommodate preLoad() methods or normal cast library loading.

- When used without a parameter, unLoad() clears from memory the cast members in all the frames of a movie.
- When used with the toMemberObjRef parameter, unLoad() clears from memory all the cast members in the range specified.

When used in a new movie with no loaded cast members, this method returns an error.
Cast members that you have modified during authoring or by setting picture, pasteClipBoardInto(), and so on, cannot be unloaded.

Parameters

`toMemberObjRef` Optional. A reference to the last cast member in the range to clear from memory.

Example
This statement clears the cast member named Ships from memory:
```
-- Lingo syntax
member("Ships").unLoad()

// JavaScript syntax
member("Ships").unLoad();
```
This statement clears from memory cast members 10 through 15:
```
-- Lingo syntax
member(10).unLoad(15)
```
// JavaScript syntax
member(10).unLoad(15);

Member

unLoad() (Movie)

Usage
-- Lingo syntax
_movie.unLoad({intFromFrameNum} {, intToFrameNum})

// JavaScript syntax
_movie.unLoad({intFromFrameNum} {, intToFrameNum});

Description
Movie method; removes the specified preloaded movie from memory.
This command is useful in forcing movies to unload when memory is low.
You can use a URL as the file reference.
If the movie isn't already in RAM, the result is -1.

Parameters
intFromFrameNum Optional. An integer that specifies the number of the first frame in a range to
unload from memory.
intToFrameNum Optional. An integer that specifies the number of the last frame in a range to
unload from memory.

Example
The following statements unload frames 10 through 25 from memory.
-- Lingo syntax
_movie.unLoad(10, 25)

// JavaScript syntax
_movie.unLoad(10, 25);

See also
Movie

unLoadMember()

Usage
-- Lingo syntax
_movie.unLoadMember({memberObjRef})
_movie.unLoadMember(fromMemberNameOrNum, toMemberNameOrNum)

// JavaScript syntax
_movie.unLoadMember({memberObjRef});
_movie.unLoadMember(fromMemberNameOrNum, toMemberNameOrNum);
Description

Movie method; forces Director to clear the cast members used in a specified frame from memory. Director automatically unloads the least recently used cast members to accommodate `preload()` methods or normal cast library loading.

* When used without an argument, the `unloadMember()` method clears from memory the cast members in all the frames of a movie.
* When used with one argument, `memberObjRef`, the `unloadMember()` method clears from memory the cast members in that frame.
* When used with two arguments, `fromMemberNameOrNum` and `toMemberNameOrNum`, the `unloadMember()` method unloads all cast members in the range specified. You can specify a range of cast members by frame numbers or frame labels.

Parameters

- `memberObjRef` Optional. A reference to the cast member to unload from memory.
- `fromMemberNameOrNum` Required if clearing a range of cast members. A string or integer that specifies the name or number of the first cast member in a range to unload from memory.
- `toMemberNameOrNum` Required if clearing a range of cast members. A string or integer that specifies the name or number of the last cast member in a range to unload from memory.

Example

This statement clears from memory the cast member Screen1:

-- Lingo syntax
_movie.unLoadMember(member("Screen1"))

// JavaScript syntax
_movie.unLoadMember(member("Screen1"));

This statement clears from memory all cast members from cast member 1 to cast member Big Movie:

-- Lingo syntax
_movie.unLoadMember(member(1), member("Big Movie"))

// JavaScript syntax
_movie.unLoadMember(member(1), member("Big Movie"));

See also

- `Movie`

`unloadMovie()`

Usage

-- Lingo syntax
_movie.unLoadMovie(stringMovieName)

// JavaScript syntax
_movie.unLoadMovie(stringMovieName);

Description

Movie method; removes the specified preloaded movie from memory.
This command is useful in forcing movies to unload when memory is low. You can use a URL as the file reference. If the movie isn't already in RAM, the result is -1.

**Parameters**

- **stringMovieName** Required. A string that specifies the name of the movie to unload from memory.

**Example**

This statement checks whether the largest contiguous block of free memory is less than 100K and unloads the movie Parsifal if it is:

```lingo
if (_system.freeBlock < (100*1024)) then
    _movie.unLoadMovie("Parsifal")
end if

// JavaScript syntax
if (_system.freeBlock < (100*1024)) {
    _movie.unLoadMovie("Parsifal");
}
```

This statement unloads the movie at http://www.cbDemille.com/SunsetBlvd.dir:

```lingo
_movie.unLoadMovie("http://www.cbDemille.com/SunsetBlvd.dir")
```

- **Movie**

---

**unregisterAllEvents**

**Usage**

```lingo
member(whichMember).unregisterAllEvents()
```

```javascript
member(whichMember).unregisterAllEvents();
```

**Description**

3D command; unregisters the referenced cast member for all event notifications. Therefore, all handlers that were previously registered to respond to events using the `registerForEvent` command will no longer be triggered when those events occur.

**Parameters**

None.

**Example**

This statement unregisters the cast member named Scene for all event notifications:

```lingo
member("Scene").unregisterAllEvents()
```
// JavaScript syntax
member("Scene").unregisterAllEvents();

See also
registerForEvent()

update

Usage
-- Lingo syntax
member(whichCastmember).model(whichModel).update

// JavaScript syntax
member(whichCastMember).model(whichModel).update();

Description
3D command; causes animations on the model to update without rendering. Use this command to find the exact position of an animating model in Lingo.

Parameters
None.

updateFrame()

Usage
-- Lingo syntax
_movie.updateFrame()

// JavaScript syntax
_movie.updateFrame();

Description
Movie method; during Score generation only, enters the changes to the current frame that have been made during Score recording and moves to the next frame. Any objects that were already in the frame when the update session started remain in the frame. You must issue an updateFrame() method for each frame that you are updating.

Parameters
None.

Example
When used in the following handler, the updateFrame command enters the changes that have been made to the current frame and moves to the next frame each time Lingo reaches the end of the repeat loop. The number of frames is determined by the argument numberOfFrames.

-- Lingo syntax
on animBall(numberOfFrames)
_movie.beginRecording()
horizontal = 0
vertical = 100
repeat with i = 1 to numberOfFrames
_movie.go(i)
sprite(20).member = member("Ball").number
sprite(20).locH = horizontal
updateStage() 571

sprite(20).locV = vertical
sprite(20).foreColor = 255
horizontal = horizontal + 3
vertical = vertical + 2
_movie.updateFrame()
end repeat
_movie.endRecording()
end animBall

// JavaScript syntax
function animBall(numberOfFrames) {
_movie.beginRecording();
var horizontal = 0;
var vertical = 100;
for (var i = 1; i <= numberOfFrames; i++) {
_movie.go();
sprite(20).member = member("Ball");
sprite(20).locH = horizontal;
sprite(20).locV = vertical;
sprite(20).foreColor = 255;
horizontal = horizontal + 3;
vertical = vertical + 2;
_movie.updateFrame();
}
_movie.endRecording();
}

See also
beginRecording(), endRecording(), Movie, scriptNum, tweened

updateStage()

Usage
-- Lingo syntax
_movie.updateStage()

// JavaScript syntax
_movie.updateStage();

Description
Movie method; redraws the Stage immediately instead of only between frames.

The updateStage() method redraws sprites, performs transitions, plays sounds, sends a prepareFrame message (affecting movie and behavior scripts), and sends a stepFrame message (which affects actorList).

Parameters
None.

Example
This handler changes the sprite’s horizontal and vertical locations and redraws the Stage so that the sprite appears in the new location without having to wait for the playhead to move:

-- Lingo syntax
on moveRight(whichSprite, howFar)
sprite(whichSprite).locH = sprite(whichSprite).locH + howFar
_movie.updateStage()
end moveRight
// JavaScript syntax
function moveRight(whichSprite, howFar) {
    sprite(whichSprite).locH = sprite(whichSprite).locH + howFar;
    _movie.updateStage();
}

See also
actorList, Movie, on prepareFrame, on stepFrame

URLEncode

Usage
URLEncode(propList_or_string \{, serverOSString\} \{, characterSet\})

Description
Function; returns the URL-encoded string for its first argument. Allows CGI parameters to be used in other commands. The same translation is done as for postNetText and getNetText() when they are given a property list.

Parameters

propListOrString Required. Specifies the property list or string to be URL-encoded.

serverOSString Optional. Encodes any return characters in propListOrString. The value defaults to "Unix" but may be set to "Win" or "Mac" and translates any carriage returns in propListOrString into those used on the server. For most applications, this setting is unnecessary because line breaks are usually not used in form responses.

characterSet Optional. Applies only if the user is running on a Shift-JIS (Japanese) system. Its possible settings are "JIS", "EUC", "ASCII", and "AUTO". Retrieved data is converted from Shift-JIS to the named character set. Returned data is handled exactly as by getNetText() (converted from the named character set to Shift-JIS). If you use "AUTO", the posted data from the local character set is not translated; the results sent back by the server are translated as they are for getNetText(). "ASCII" is the default if characterSet is omitted. "ASCII" provides no translation for posting or results.

Example
In the following example, URLEncode supplies the URL-encoded string to a CGI query at the specified location.

URL = "http://aserver/cgi-bin/echoquery.cgi"
gotonetpage URL & "?" & URLEncode( [\#name: "Ken", \#hobby: "What?"] )

See also
getNetText(), postNetText

value()

Usage
value(stringExpression)

Description
Function; returns the value of a string. When value() is called, Lingo parses through the stringExpression provided and returns its logical value.
Any Lingo expression that can be put in the Message window or set as the value of a variable can also be used with value().

These two Lingo statements are equivalent:

```lingo
put sprite(2).member.duration * 5
put value("sprite(2).member.duration * 5")
```

These two Lingo statements are also equivalent:

```lingo
x = (the mouseH - 10) / (the mouseV + 10)
x = value("(the mouseH - 10) / (the mouseV + 10)")
```

Expressions that Lingo cannot parse will produce unexpected results, but will not produce Lingo errors. The result is the value of the initial portion of the expression up to the first syntax error found in the string.

The value() function can be useful for parsing expressions input into text fields by end-users, string expressions passed to Lingo by Xtra extensions, or any other expression you need to convert from a string to a Lingo value.

Keep in mind that there may be some situations where using value() with user input can be dangerous, such as when the user enters the name of a custom handler into the field. This will cause the handler to be executed when it is passed to value().

Do not confuse the actions of the value function with the integer() and float() functions.

**Parameters**

`stringExpression` Required. Specifies the string from which a value is returned. The string can be any expression that Lingo can understand.

**Example**

This statement displays the numerical value of the string "the sqrt of" && "2.0":

```lingo
put value("the sqrt of" && "2.0")
```

The result is 1.4142.

This statement displays the numerical value of the string "penny":

```lingo
put value("penny")
```

The resulting display in the Message window is VOID, because the word penny has no numerical value.

You can convert a string that is formatted as a list into a true list by using this syntax:

```lingo
myString = "[" & QUOTE & "cat" & QUOTE & ", " & QUOTE & "dog" & QUOTE & "]"
myList = value(myString)
put myList
-- ["cat", "dog"]
```

This allows a list to be placed in a field or text cast member and then extracted and easily reformatted as a list.

This statement parses the string "3 5" and returns the value of the portion of the string that Lingo understands:

```lingo
put value("3 5")
-- 3
```
See also

string(), integer(), float()

vector()

Usage

-- Lingo syntax
vector()
vector(intX, intY, intZ)

// JavaScript syntax
vector();
vector(intX, intY, intZ);

Description

Top level function and data type. Describes a point in 3D space according to three parameters, which are the specific distances from the reference point along the x-axis, y-axis, and z-axis, respectively.

If the vector is in world space, the reference point is the world origin, vector(0, 0, 0). If the vector is in object space, the reference point is the object's position and orientation.

This method returns a vector object.

Vector values can be operated upon by the +, -, * and / operators. See their individual definitions for more information.

Parameters

intX Optional. An integer that specifies the x-axis point.
intY Optional. An integer that specifies the y-axis point.
intZ Optional. An integer that specifies the z-axis point.

Example

This statement creates a vector and assigns it to the variable myVector:

-- Lingo syntax
myVector = vector(10.0, -5.0, 0.0)

// JavaScript syntax
var myVector = vector(10.0, -5.0, 0.0);

In Lingo only, this statement adds two vectors and assigns the resulting value to the variable thisVector:

-- Lingo syntax
thisVector = vector(1.0, 0.0, 0.0) + vector(0.0, -12.5, 2.0)

version()

Usage

-- Lingo syntax
fileioObjRef.version()

// JavaScript syntax
fileioObjRef.version();
Description

Fileio method; Displays the Fileio version and build information in the Message window.

Parameters

None.

See also

Fileio

voiceCount()

Usage

voiceCount()

Description

Function: returns the number of installed voices available to the text-to-speech engine. The return value is an integer. This number of voices can be used with voiceSet() and voiceGet() to specify a particular voice to be active.

Parameters

None.

Example

This statement sets the variable numVoices to the number of available text-to-speech voices:
numVoices = voiceCount()

See also

voiceInitialize(), voiceSet(), voiceGet()

voiceGet()

Usage

voiceGet()

Description

Function; returns a property list describing the current voice being used for text-to-speech. The list contains the following properties:

- #name indicates the name of the installed voice.
- #age indicates the age of the voice. The value is a string. Possible values include “Teen”, “Adult”, “Toddler”, and “Senior”, as well as numeric values such as “35”. Actual values depend on the operating system, speech software version, and voices installed.
- #gender indicates whether the voice is male or female. The value is a string.
- #index indicates the position of the voice in the list of installed voices. You can refer to a voice by its index when using the voiceSet() command.

Use voiceCount() to determine the number of available voices.
Parameters

None.

Example

This statement sets the variable oldVoice to the property list describing the current text-to-speech voice:

oldVoice = voiceGet()

This statement displays the property list of the current text-to-speech voice:

put voiceGet()
-- [#name: "Mary", #age: "teen", #gender: "female", #index: 5]

See also

voiceInitialize(), voiceCount(), voiceSet(), voiceGet()

voiceGetAll()

Usage

voiceGetAll()

Description

Function; returns a list of the available voices installed on the computer. The list is composed of property lists, one for each available voice.

Each property list contains the following properties:

• #name indicates the name of the installed voice.
• #age indicates the age of the voice. The value is a string. Possible values include “Teen”, “Adult”, “Toddler”, and “Senior”, as well as numeric values such as “35”. Actual values depend on the operating system, speech software version, and voices installed.
• #gender indicates whether the voice is male or female.
• #index indicates the position of the voice in the list of installed voices. You can refer to a voice by its index when using the voiceSet() command.

You can also use voiceCount() to determine the number of available voices.

Parameters

None.

Example

This statement sets the variable currentVoices to the list of voices installed on the user’s computer:

currentVoices = voiceGetAll()

This statement displays the property list describing each of the currently installed text-to-speech voices:

put voiceGetAll()
-- [[#name: "Mary", #age: "teen", #gender: "female", #index: 1], [#name: "Joe", #age: "adult", #gender: "male", #index: 2]]
voiceGetPitch()

Usage
voiceGetPitch()

Description
Function; returns the current pitch for the current voice as an integer. The valid range of values depends on the operating system platform and text-to-speech software.

Parameters
None.

Example
These statements check whether the pitch of the current voice is above 10 and set it to 10 if it is:
   -- Lingo syntax
   if voiceGetPitch() > 10 then
       voiceSetPitch(10)
   end if
   
   // JavaScript syntax
   if (voiceGetPitch() > 10) {
       voiceSetPitch(10);
   }

See also
voiceInitialze(), voiceCount(), voiceSet(), voiceGet()

voiceGetRate()

Usage
voiceGetRate()

Description
Function; returns the current playback rate of the text-to-speech engine. The return value is an integer. The valid range of values depends on the text-to-speech software and operating system platform. In general, values between -10 and 10 can be expected.

Parameters
None.

Example
These statements check whether the rate of speech synthesis is below 50 and set it to 50 if it is:
   -- Lingo syntax
   if voiceGetRate() < 50 then
       voiceSetRate(50)
   end if
// JavaScript syntax
if (voiceGetRate() < 50) {
  voiceSetRate(50);
}

See also
voiceSpeak(), voicePause(), voiceResume(), voiceStop(), voiceGetRate(),
voiceGetPitch(), voiceSetPitch(), voiceGetVolume(), voiceSetVolume(),
voiceState(), voiceWordPos()

voiceGetVolume()

Usage
voiceGetVolume()

Description
Function: returns the current volume of the text-to-speech synthesis. The value returned is an integer. The valid range of values depends on the operating system platform.

Parameters
None.

Example
These statements check whether the text-to-speech volume is at least 55 and set it to 55 if is lower:
-- Lingo syntax
if voiceGetVolume() < 55 then
  voiceSetVolume(55)
end if

// JavaScript syntax
if (voiceGetVolume() < 55) {
  voiceSetVolume(55);
}

See also
voiceSpeak(), voicePause(), voiceResume(), voiceStop(), voiceGetRate(),
voiceGetPitch(), voiceSetPitch(), voiceGetVolume(), voiceSetVolume(),
voiceState(), voiceWordPos()

voiceInitialize()

Usage
voiceInitialize()

Description
Command; loads the computer's text-to-speech engine. If the voiceInitialize() command returns 0, text-to-speech software is not present or failed to load.

The command returns 1 if successful, 0 otherwise.

Parameters
None.
Example

These statements load the computer's text-to-speech engine and then test for whether the text-to-speech engine has completed loading before using the `voiceSpeak()` command to speak the phrase “Welcome to Shockwave.”:

```-- Lingo syntax
err = voiceInitialize()
if err = 1 then
    voiceSpeak("Welcome to Shockwave")
else
    alert "Text-to-speech software failed to load."
end if
```

```// JavaScript syntax
err = voiceInitialize();
if (err == 1) {
    voiceSpeak("Welcome to Shockwave");
} else {
    alert("Text-to-speech software failed to load.");
}
```

See also

`voiceCount()`, `voiceSet()`, `voiceGet()`

voicePause()

**Usage**

`voicePause()`

**Description**

Command; pauses the speech output to the text-to-speech engine. The command returns a value of 1 if it is successful, or 0 if it is not.

**Parameters**

None.

**Example**

These statements cause the text-to-speech engine to pause when the user clicks the mouse:

```-- Lingo syntax
on mouseUp
    voicePause()
end mouseUp
```

```// JavaScript syntax
function mouseUp() {
    voicePause();
}
```

See also

`voiceSpeak()`, `voiceResume()`, `voiceStop()`, `voiceGetRate()`, `voiceSetRate()`, `voiceGetPitch()`, `voiceSetPitch()`, `voiceGetVolume()`, `voiceSetVolume()`, `voiceState()`, `voiceWordPos()`
**voiceResume()**

**Usage**

voiceResume()

**Description**

Command; resumes the speech output to the text-to-speech engine. The command returns a value of 1 if it is successful, or 0 if it is not.

**Parameters**

None.

**Example**

These statements resume the speech when the playhead moves to the next frame in the Score:

```-- Lingo syntax
on exitFrame
    voiceResume()
end exitFrame

// JavaScript syntax
function exitFrame() {
    voiceResume();
}
```

**See also**

voiceSpeak(), voicePause(), voiceStop(), voiceGetRate(), voiceSetRate(), voiceGetPitch(), voiceSetPitch(), voiceGetVolume(), voiceSetVolume(), voiceState(), voiceWordPos()

---

**voiceSet()**

**Usage**

voiceSet(integer)

**Description**

Command: Sets the current voice of the text-to-speech synthesis. If successful, the command returns the new value that was set. Use voiceCount() to determine the number of available voices.

**Parameters**

*integer* Required. An integer that specifies the number of the text-to-speech voice to use. The valid range of values depends on the number of voices installed on the user's computer. If an out-of-range value is specified, the voice is set to the nearest valid value.

**Example**

This statement sets the current text-to-speech voice to the third voice installed on the user's computer:

```voiceSet(3)```

**See also**

voiceInitialize(), voiceCount(), voiceGet()
voiceSetPitch()

Usage
voiceSetPitch(integer)

Description
Command; sets the pitch for the current voice of the text-to-speech engine to the specified value. The return value is the new pitch value that has been set.

Parameters
integer Required. An integer that specifies the pitch for the text-to-speech voice. The valid range of values depends on the operating system platform and text-to-speech software.

Example
This statement sets the pitch for the current voice to 75:
voiceSetPitch(75)

See also
voiceSpeak(), voicePause(), voiceResume(), voiceStop(), voiceGetRate(), voiceSetRate(), voiceGetPitch(), voiceGetVolume(), voiceSetVolume(), voiceState(), voiceWordPos()

voiceSetRate()

Usage
voiceSetRate(integer)

Description
Command; sets the playback rate of the text-to-speech engine to the specified integer value. The command returns the new value that has been set.

Parameters
integer Required. An integer that specifies the playback rate that the text-to-speech engine uses. The valid range of values depends on the operating system platform. In general, values between -10 and 10 are appropriate for most text-to-speech software. If an out-of-range value is specified, the rate will be set to the nearest valid value.

Example
This statement sets the playback rate of the text-to-speech engine to 7:
voiceSetRate(7)

See also
voiceSpeak(), voicePause(), voiceResume(), voiceStop(), voiceGetRate(), voiceSetRate(), voiceGetPitch(), voiceSetPitch(), voiceGetVolume(), voiceSetVolume(), voiceState(), voiceWordPos()
voiceSetVolume()

Usage

voiceSetVolume(integer)

Description

Command; sets the volume of the text-to-speech synthesis.

Parameters

integer Required. An integer that specifies the volume of text-to-speech synthesis. The range of valid values depends on the operating system platform. If successful, the command returns the new value that was set. If an invalid value is specified, the volume is set to the nearest valid value.

Example

This statement sets the volume of text-to-speech synthesis to 55:

voiceSetVolume(55)

See also

voiceSpeak(), voicePause(), voiceResume(), voiceStop(), voiceGetRate(), voiceSetRate(), voiceGetPitch(), voiceSetPitch(), voiceGetVolume(), voiceState(), voiceWordPos()

voiceSpeak()

Usage

-- Lingo syntax
voiceSpeak("string")

// JavaScript syntax
voiceSpeak("string"); // documentation n/a

Description

Command; causes the specified string to be spoken by the text-to-speech engine. When this command is used, any speech currently in progress is interrupted by the new string.

Parameters

string Required. The string to be spoken by the text-to-speech engine.

Example

This statement causes the text-to-speech engine to speak the string “Welcome to Shockwave”:

voiceSpeak("Welcome to Shockwave")

See also

voiceSpeak(), voicePause(), voiceResume(), voiceStop(), voiceGetRate(), voiceSetRate(), voiceGetPitch(), voiceSetPitch(), voiceGetVolume(), voiceState(), voiceWordPos()
voiceState()

**Usage**

-- Lingo syntax
voiceState()

// JavaScript syntax
voiceState(); // documentation n/a

**Description**

Function; returns the current status of the voice as a symbol. The possible return values are #playing, #paused, and #stopped.

**Parameters**

None.

**Example**

These statements check whether the text-to-speech engine is actively speaking and set the voice to 1 if it is not:

--Lingo syntax
if voiceState() <> #playing then
    voiceSet(1)
end if

// JavaScript syntax
if (voiceState() != symbol("playing")) {
    voiceSet(1);
}

**See also**

voiceSpeak(), voicePause(), voiceResume(), voiceStop(), voiceGetRate(), voiceSetRate(), voiceGetPitch(), voiceSetPitch(), voiceGetVolume(), voiceSetVolume(), voiceWordPos(), voiceSpeak()

voiceStop()

**Usage**

-- Lingo syntax
voiceStop()

// JavaScript syntax
voiceStop(); // documentation n/a

**Description**

Command; stops the speech output to the text-to-speech engine and empties the text-to-speech buffer. The command returns a value of 1 if it is successful, or 0 if it is not.

**Parameters**

None.
Example

These statements stop the speech when the playhead moves to the next frame in the Score:

-- Lingo syntax
on exitFrame
  voiceStop()
end exitFrame

// JavaScript syntax
function exitFrame() {
  voiceStop();
}

See also
voiceSpeak(), voicePause(), voiceResume(), voiceGetRate(), voiceSetRate(),
voiceGetPitch(), voiceSetPitch(), voiceGetVolume(), voiceSetVolume(),
voiceState(), voiceWordPos(), voiceSpeak()

voiceWordPos()

Usage

-- Lingo syntax
voiceWordPos()

// JavaScript syntax
voiceWordPos(); // documentation n/a

Description

Function; returns an integer indicating the position of the word that is currently being spoken
within the entire string that contains it. For example, if a cast member containing 15 words is
being spoken and the fifth word of the cast member is being spoken when the function is used,
the return value is 5.

Parameters

None.

Example

The following statements cause the sentence “Hello, how are you?” to be spoken and display the
current word position in the Message window. Since the voiceWordPos() function is called
immediately after the voiceSpeak() command is used, the return value will be 1.

-- Lingo syntax
voiceSpeak("Hello, how are you?"
put voiceWordPos()
-- 1

// JavaScript syntax
voiceSpeak("Hello, how are you?");
put(voiceWordPos());
// 1

See also
voiceSpeak(), voicePause(), voiceResume(), voiceStop(), voiceGetRate(),
voiceSetRate(), voiceGetPitch(), voiceSetPitch(), voiceGetVolume(),
voiceSetVolume(), voiceState(), voiceSpeak()
voidP()

Usage
-- Lingo syntax
voidP(variableName)

// JavaScript syntax
variableName == null

Description
Function; determines whether a specified variable has any value. If the variable has no value or
is VOID, this function returns TRUE. If the variable has a value other than VOID, this function
returns FALSE.

Parameters
variableName Required. Specifies the variable to test.

Example
This statement checks whether the variable answer has an initial value:
-- Lingo syntax
put voidP(answer)

// JavaScript syntax
put(answer == null));

See also
ilk(), VOID

window()

Usage
-- Lingo syntax
window(stringWindowName)

// JavaScript syntax
window(stringWindowName);

Description
Top level function; returns a reference to a specified window.
The specified window must contain a Director movie.
Windows that play movies are useful for creating floating palettes, separate control panels, and
windows of different shapes. Using windows that play movies, you can have several movies open
at once and allow them to interact.

Parameters
stringWindowName Required. A string that specifies the name of the window to reference.
Example

This statement sets the variable `myWindow` to the window named Collections:

```-- Lingo syntax
myWindow = window("Collections")
```

```// JavaScript syntax
var myWindow = window("Collections");
```

See also

Window

```windowPresent()```

Usage

```-- Lingo syntax
_player.windowPresent(stringWindowName)
```

```// JavaScript syntax
_player.windowPresent(stringWindowName);
```

Description

Player method; indicates whether the object specified by `stringWindowName` is running as a movie in a window (TRUE) or not (FALSE).

If a window had been opened, `windowPresent()` remains TRUE for the window until the window has been removed from the `windowList` property.

The `stringWindowName` argument must be the window's name as it appears in the `windowList` property.

Parameters

`stringWindowName` Required. A string that specifies the name of the window to test.

Example

This statement tests whether the object `myWindow` is a movie in a window (MIAW) and then displays the result in the Message window:

```-- Lingo syntax
put(_player.windowPresent(myWindow))
```

```// JavaScript syntax
put(_player.windowPresent(myWindow));
```

See also

Player, windowList
worldSpaceToSpriteSpace

Usage

-- Lingo syntax
member(whichCastmember).camera(whichCamera).worldSpaceToSpriteSpace(vector)

// JavaScript syntax
member(whichCastmember).camera(whichCamera).worldSpaceToSpriteSpace(vector);

Description

3D command; returns the point within the camera's rect at which a specified world-relative position would appear. The position returned by this command is relative to the upper left corner of the camera's rect.

If the position specified is out of view of the camera, this command returns void.

Parameters

vector Required. Specifies the world-relative position that would appear.

Example

This statement shows that the world origin, specified by vector (0, 0, 0), appears at point (250, 281) within the camera's rect:

-- Lingo syntax
put sprite(5).camera.worldSpaceToSpriteSpace(vector(0, 0, 0))
-- point(250, 281)

// JavaScript syntax
put(sprite(5).camera.worldSpaceToSpriteSpace(vector(0, 0, 0)));

See also

spriteSpaceToWorldSpace, rect (camera)

writeChar()

Usage

-- Lingo syntax
fileioObjRef.writeChar(stringChar)

// JavaScript syntax
fileioObjRef.writeChar(stringChar)

Description

Fileio method; Writes a single specified ASCII character to a file.

You must first open a file by calling openFile() before using writeChar() to write a character.

Parameters

stringChar Required. Specifies the ASCII character to write to the file.

See also

Fileio
writeReturn()

**Usage**

--- Lingo syntax
```lingo
fileioObjRef.writeReturn()
```

// JavaScript syntax
```javascript
FileioObjRef.writeReturn();
```

**Description**

Fileio method; Inserts a line return in a file.

**Parameters**

None.

**See also**

Fileio

writeString()

**Usage**

--- Lingo syntax
```lingo
fileioObjRef.writeString(string)
```

// JavaScript syntax
```javascript
FileioObjRef.writeString(string)
```

**Description**

Fileio method; Writes a null-terminated string to a file.

**Parameters**

`string` Required. The string to write to a file.

**See also**

Fileio

xtra()

**Usage**

--- Lingo syntax
```lingo
xtra(xtraNameOrNum)
```

// JavaScript syntax
```javascript
xtra(xtraNameOrNum);
```

**Description**

Top level function; returns an instance of a specified Xtra.

A reference to an empty object is returned if the specified Xtra is not found.

To see an example of `xtra` used in a completed movie, see the Read and Write Text movie in the Learning/Lingo folder inside the Director application folder.
Parameters

\textit{xtraNameOrNum} Required. A string that specifies the name of the Xtra to return, or an integer that specifies the index position of the Xtra to return. String names are not case sensitive.

Example

This statement sets the variable \textit{myNetLingo} to the NetLingo Xtra extension:

\begin{verbatim}
  -- Lingo syntax
  myNetLingo = xtra("netlingo")

  // JavaScript syntax
  var myNetLingo = xtra("netlingo");
\end{verbatim}

\textbf{zoomBox}

Usage

\begin{verbatim}
  -- Lingo syntax
  zoomBox startSprite, endSprite [,delayTicks]

  // JavaScript syntax
  zoomBox(startSprite, endSprite [,delayTicks]); // not yet documented
\end{verbatim}

Description

Command; creates a zooming effect, like the expanding windows in the Macintosh Finder. The zoom effect starts at a bounding rectangle of a specified starting sprite and finishes at the bounding rectangle of a specified ending sprite. The \texttt{zoomBox} command uses the following logic when executing:

1. Look for \texttt{endSprite} in the current frame; otherwise,
2. Look for \texttt{endSprite} in the next frame.

Note, however, that the \texttt{zoomBox} command does not work for \texttt{endSprite} if it is in the same channel as \texttt{startSprite}.

Parameters

\textit{startSprite} Required. Specifies the starting sprite.

\textit{endSprite} Required. Specifies the ending sprite.

\textit{delayTicks} Optional. Specifies the delay in ticks between each movement of the zoom rectangles. If \texttt{delayTicks} is not specified, the delay is 1.

Example

This statement creates a zoom effect between sprites 7 and 3:

\begin{verbatim}
  -- Lingo syntax
  zoomBox 7, 3

  // JavaScript syntax
  zoomBox(7, 3); // not yet documented
\end{verbatim}
This section provides an alphabetical list of all the operators available in Macromedia Director MX 2004.

The majority of these operators apply only to Lingo. JavaScript syntax does contain some operators that are either similar or identical to the Lingo operators listed here; therefore, where appropriate, JavaScript syntax usage and examples are provided to help you map the functionality of Lingo operators with their closest counterparts in JavaScript syntax. For more information about JavaScript syntax operators, see Chapter 2, “Director Scripting Essentials,” on page 9.

# (symbol)

Usage

- Lingo syntax
  \#symbolName

// JavaScript syntax
symbol("symbolName");

Description

Symbol operator; defines a symbol, a self-contained unit that can be used to represent a condition or flag. The value `symbolName` begins with an alphabetical character and may be followed by any number of alphabetical or numerical characters.

A symbol can do the following:

- Assign a value to a variable.
- Compare strings, integers, rectangles, and points.
- Pass a parameter to a handler or method.
- Return a value from a handler or method.

A symbol takes up less space than a string and can be manipulated, but unlike a string it does not consist of individual characters. You can convert a symbol to a string for display purposes by using the `string` function.

The following are some important points about symbol syntax:

- Symbols are not case-sensitive.
- Symbols can't start with a number.
- Spaces may not be used, but you can use underscore characters to simulate them.
• Symbols use the 128 ASCII characters, and letters with diacritical or accent marks are treated as their base letter.
• Periods may not be used in symbols.

All symbols, global variables, and names of parameters passed to global variables are stored in a common lookup table.

Example
This statement sets the state variable to the symbol #Playing:

-- Lingo syntax
state = #Playing

// JavaScript syntax
var state = symbol("Playing");

See also
ilk(), string(), symbol(), symbolP()

. (dot operator)

Usage
-- Lingo syntax
objectReference.objectProperty
textExpression.objectProperty
object.commandOrFunction()

// JavaScript syntax
objectReference.objectProperty;
textExpression.objectProperty;
object.commandOrFunction();

Description
Operator; used to test or set properties of objects, or to issue a command or execute a function of the object. The object may be a cast member, a sprite, a property list, a child object of a parent script, or a behavior.

Example
This statement displays the current member contained by the sprite in channel 10:

-- Lingo syntax
put(sprite(10).member)

// JavaScript syntax
put(sprite(10).member);

To use the alternate syntax and call a function, you can use this form:

-- Lingo syntax
myColorObject = color(124, 22, 233)
put(myColorObject.ilk())
-- #color

// JavaScript syntax
var myColorObject = color(124, 22, 233);
put(myColorObject.ilk());
// #color
- (minus)

Usage

-- Lingo syntax
(Negation): expression
(Subtraction): expression1 - expression2

// JavaScript syntax
(Negation): expression
(Subtraction): expression1 - expression2

Description

Math operator; when used for negation, - (minus) reverses the sign of the value of expression; when used for subtraction, - (minus) performs an arithmetic subtraction on two numerical expressions, subtracting expression2 from expression1.

When used for negation, - (minus) is an arithmetic operator with a precedence level of 5.

When used for subtraction, both expressions are integers, the difference is an integer. When either or both expressions are floating-point numbers, the difference is a floating-point number. The - (minus) operator is an arithmetic operator with a precedence level of 3.

Example

(Negation): This statement reverses the sign of the expression 2 + 3:
-- Lingo syntax
put(-(2 + 3))

// JavaScript syntax
put(-(2 + 3));

The result is -5.

(Subtraction): This statement subtracts the integer 2 from the integer 5 and displays the result in the Message window:
-- Lingo syntax
put(5 - 2)

// JavaScript syntax
put(5 - 2);

The result is 3, which is an integer.

(Subtraction): This statement subtracts the floating-point number 1.5 from the floating-point number 3.25 and displays the result in the Message window:
-- Lingo syntax
put(3.25 - 1.5)

// JavaScript syntax
put(3.25 - 1.5);

The result is 1.75, which is a floating-point number.
-- (comment)

Usage

-- Lingo syntax
-- comment

// JavaScript syntax
// comment

Description

Comment delimiter; indicates the beginning of a script comment. On any line, anything that appears between the comment delimiter (double hyphen) and the end-of-line return character is interpreted as a comment rather than a Lingo statement.

Example

This handler uses a double hyphen to make the second, fourth, and sixth lines comments:

-- Lingo syntax
on resetColors
  -- This handler resets the sprite’s colors.
  sprite(1).forecolor = 35
  -- bright red
  sprite(1).backcolor = 36
  -- light blue
end

// JavaScript syntax
function resetColors() {
  // this handler resets the sprite’s colors
  sprite(1).forecolor = 35;
  // bright red
  sprite(1).backcolor = 36;
  // light blue
}

&, + (concatenation operator)

Usage

-- Lingo syntax
expression1 & expression2

// JavaScript syntax
expression1 + expression2

Description

String operator; performs a string concatenation of two expressions. If either expression1 or expression2 is a number, it is first converted to a string. The resulting expression is a string.

This is a string operator with a precedence level of 2.

Lingo allows you to use some commands and functions that take only one argument without parentheses surrounding the argument. When an argument phrase includes an operator, Lingo interprets only the first argument as part of the function, which may confuse Lingo.
Avoid this problem by placing parentheses around the entire phrase that includes an operator. The parentheses clear up Lingo's confusion by changing the precedence by which Lingo deals with the operator, causing Lingo to treat the two parts of the argument as one complete argument.

Example

This statement concatenates the strings "abra" and "cadabra" and displays the resulting string in the Message window:

-- Lingo syntax
put("abra" & "cadabra")

// JavaScript syntax
put("abra" + "cadabra");

The result is the string “abracadabra”.

This statement concatenates the strings "$" and the content of the price variable and then assigns the concatenated string to the Price field cast member:

-- Lingo syntax
member("Price").text = "$" & price

// JavaScript syntax
member("Price").text = "$" + price;

&&, + (concatenation operator)

Usage

-- Lingo syntax
expression1 && expression2

// JavaScript syntax
expression1 + expression2

Description

String operator; concatenates two expressions, inserting a space character between the original string expressions. If either expression1 or expression2 is a number, it is first converted to a string. The resulting expression is a string.

This is a string operator with a precedence level of 2.

Example

This statement concatenates the strings "abra" and "cadabra" and inserts a space between the two:

-- Lingo syntax
put("abra" && "cadabra")

// JavaScript syntax
put("abra " + "cadabra");

The result is the string “abra cadabra”.

&&, + (concatenation operator) 595
This statement concatenates the strings “Today is” and today’s date in the long format and inserts a space between the two:

-- Lingo syntax
put("Today is" && date())

// JavaScript syntax
put("Today is " + Date());

() (parentheses)

Usage

-- Lingo syntax
(expression)

// JavaScript syntax
(expression)

Description

Grouping operator; performs a grouping operation on an expression to control the order of execution of the operators in an expression. This operator overrides the automatic precedence order so that the expression within the parentheses is evaluated first. When parentheses are nested, the contents of the inner parentheses are evaluated before the contents of the outer ones.

This is a grouping operator with a precedence level of 5.

Be aware that Lingo allows you to use some commands and functions that take only one argument without parentheses surrounding the argument. When an argument phrase includes an operator, Lingo interprets only the first argument as part of the function, which may confuse Lingo.

For example, the open window command allows one argument that specifies which window to open. If you use the & operator to define a pathname and filename, Director interprets only the string before the & operator as the filename. For example, Lingo interprets the statement open window the applicationPath & "theMovie" as (open window the applicationPath) & ("theMovie"). Avoid this problem by placing parentheses around the entire phrase that includes an operator, as follows:

-- Lingo syntax
open window (the applicationPath & "theMovie")

// JavaScript syntax
window(the applicationPath + "theMovie").open();

Example

These statements use the grouping operator to change the order in which operations occur (the result appears below each statement):

-- Lingo syntax
put((2 + 3) * (4 + 5))
-- 45
put(2 + (3 * (4 + 5)))
-- 29
put(2 + 3 * 4 + 5)
-- 19
// JavaScript syntax
put((2 + 3) * (4 + 5)); // 45
put(2 + (3 * (4 + 5)));
// 29
put(2 + 3 * 4 + 5);
// 19

* (multiplication)

Usage
-- Lingo syntax
expression1 * expression2

// JavaScript syntax
expression1 * expression2

Description
Math operator; performs an arithmetic multiplication on two numerical expressions. If both expressions are integers, the product is an integer. If either or both expressions are floating-point numbers, the product is a floating-point number.

This is an arithmetic operator with a precedence level of 4.

Example
This statement multiplies the integers 2 and 3 and displays the result in the Message window:

-- Lingo syntax
put(2 * 3)

// JavaScript syntax
put(2 * 3);

The result is 6, which is an integer.

This statement multiplies the floating-point numbers 2.0 and 3.1414 and displays the result in the Message window:

-- Lingo syntax
put(2.0 * 3.1416)

// JavaScript syntax
put(2.0 * 3.1416);

The result is 6.2832, which is a floating-point number.
+ (addition)

Usage
-- Lingo syntax
expression1 + expression2

// JavaScript syntax
expression1 + expression2

Description
Math operator; performs an arithmetic sum on two numerical expressions. If both expressions are
integers, the sum is an integer. If either or both expressions are floating-point numbers, the sum is
a floating-point number.

This is an arithmetic operator with a precedence level of 4.

Example
This statement adds the integers 2 and 3 and then displays the result, 5, an integer, in the
Message window:
-- Lingo syntax
put(2 + 3)

// JavaScript syntax
put(2 + 3);

This statement adds the floating-point numbers 2.5 and 3.25 and displays the result, 5.7500, a
floating-point number, in the Message window:
-- Lingo syntax
put(2.5 + 3.25)

// JavaScript syntax
put(2.5 + 3.25);

+ (addition) (3D)

Usage
-- Lingo syntax
vector1 + vector2
vector + scalar

// JavaScript syntax
vector1 + vector2
vector + scalar

Description
3D vector operator; adds the components of two vectors, or adds the scalar value to each
component of the vector and returns a new vector.

vector1 + vector2 adds the components of vector1 to the corresponding to components of
vector2 and returns a new vector.

vector + scalar adds the scalar value to each of the components of the vector and returns a
new vector.
- (subtraction)

Usage

-- Lingo syntax
vector1 - vector2
vector - scalar

// JavaScript syntax
vector1 - vector2
vector - scalar

Description

3D vector operator; subtracts the components of vector2 from the corresponding components of vector1, or subtracts the scalar value from each of the components and returns a new vector.

vector1 - vector2 subtracts the values of vector2 from the corresponding components in vector1 and returns a new vector.

vector - scalar subtracts the value of the scalar from each of the components in the vector and returns a new vector.

* (multiplication)

Usage

-- Lingo syntax
vector1 * vector2
vector * scalar
transform * vector

// JavaScript syntax
vector1 * vector2
vector * scalar
transform * vector

Description

3D vector operator; multiplies the components of vector1 by the corresponding components in vector2, and returns the dot product, or multiplies each of the components the vector by the scalar value and returns a new vector.

vector1 * vector2 returns the dot product of the two vectors, which is not a new vector. This operation is the same as vector1.dotproduct.vector2.

vector * scalar multiplies each of the components in the vector by the scalar value and returns a new vector.

transform * vector multiplies the transform by the vector and returns a new vector. The new vector is the result of applying the positional and rotational changes defined by transform to the vector. Note that vector * transform is not supported.

See also

dotProduct()
/ (division)

Usage
-- Lingo syntax
expression1 / expression2

// JavaScript syntax
expression1 / expression2

Description
Math operator; performs an arithmetic division on two numerical expressions, dividing
expression1 by expression2. If both expressions are integers, the quotient is an integer. If
either or both expressions are floating-point numbers, the quotient is a floating-point number.
This is an arithmetic operator with a precedence level of 4.

Example
This statement divides the integer 22 by 7 and then displays the result in the Message window:

-- Lingo syntax
put(22 / 7)

// JavaScript syntax
put(22 / 7):

The result is 3. Because both numbers in the division are integers, Lingo rounds the answer down
to the nearest integer.

This statement divides the floating-point number 22.0 by 7.0 and then displays the result in the
Message window:

-- Lingo syntax
put(22.0 / 7.0)

// JavaScript syntax
put(22.0 / 7.0):

The result is 3.1429, which is a floating-point number.

/ (division) (3D)

Usage
-- Lingo syntax
vector / scalar

// JavaScript syntax
vector / scalar

Description
3D vector operator; divides each of the vector components by the scalar value and returns a
new vector.
< (less than)

Usage

-- Lingo syntax
expression1 < expression2

// JavaScript syntax
expression1 < expression2

Description
Comparison operator; compares two expressions and determines whether \textit{expression1} is less than \textit{expression2} (TRUE), or whether \textit{expression1} is greater than or equal to \textit{expression2} (FALSE).

This operator can compare strings, integers, floating-point numbers, rects, and points. Be aware that comparisons performed on rects or points are handled as if the terms were lists, with each element of the first list compared to the corresponding element of the second list.

This is a comparison operator with a precedence level of 1.

<= (less than or equal to)

Usage

-- Lingo syntax
expression1 <= expression2

// JavaScript syntax
expression1 <= expression2

Description
Comparison operator; compares two expressions and determines whether \textit{expression1} is less than or equal to \textit{expression2} (TRUE), or whether \textit{expression1} is greater than \textit{expression2} (FALSE).

This operator can compare strings, integers, floating-point numbers, rects, and points. Be aware that comparisons performed on rects or points are handled as if the terms were lists, with each element of the first list compared to the corresponding element of the second list.

This is a comparison operator with a precedence level of 1.

<> (not equal)

Usage

-- Lingo syntax
expression1 <> expression2

// JavaScript syntax
expression1 != expression2

Description
Comparison operator; compares two expressions, symbols, or operators and determines whether \textit{expression1} is not equal to \textit{expression2} (TRUE), or whether \textit{expression1} is equal to \textit{expression2} (FALSE).
This operator can compare strings, integers, floating-point numbers, rects, and points. Be aware that comparisons performed on rects or points are handled as if the terms were lists, with each element of the first list compared to the corresponding element of the second list.

This is a comparison operator with a precedence level of 1.

= (equals)

Usage

-- Lingo syntax
expression1 = expression2

// JavaScript syntax
expression1 = expression2

Description

Comparison operator; compares two expressions, symbols, or objects and determines whether expression1 is equal to expression2 (TRUE), or whether expression1 is not equal to expression2 (FALSE).

This operator can compare strings, integers, floating-point numbers, rects, lists, and points.

Lists are compared based on the number of elements in the list. The list with more elements is considered larger than the list with fewer elements.

This is a comparison operator with a precedence level of 1.

> (greater than)

Usage

-- Lingo syntax
expression1 > expression2

// JavaScript syntax
expression1 > expression2

Description

Comparison operator; compares two expressions and determines whether expression1 is greater than expression2 (TRUE), or whether expression1 is less than or equal to expression2 (FALSE).

This operator can compare strings, integers, floating-point numbers, rects, and points. Be aware that comparisons performed on rects or points are handled as if the terms were lists, with each element of the first list compared to the corresponding element of the second list.

This is a comparison operator with a precedence level of 1.
>= (greater than or equal to)

Usage

-- Lingo syntax
expression1 >= expression2

// JavaScript syntax
expression1 >= expression2

Description
Comparison operator; compares two expressions and determines whether \textit{expression1} is greater than or equal to \textit{expression2} (\texttt{TRUE}), or whether \textit{expression1} is less than \textit{expression2} (\texttt{FALSE}).

This operator can compare strings, integers, floating-point numbers, rects, and points. Be aware that comparisons performed on rectangles or points are handled as if the terms were lists, with each element of the first list compared to the corresponding element of the second list.

This is a comparison operator with a precedence level of 1.

[ ] (bracket access)

Usage

-- Lingo syntax
textExpression[chunkNumberBeingAddressed]
textExpression[firstChunk..lastChunk]

Description
Operator; allows a chunk expression to be addressed by number. Useful for finding the \textit{n}th chunk in the expression. The chunk can be a word, line, character, paragraph, or other Text cast member chunk.

Example
This outputs the first word of the third line in the text cast member First Names:

-- Lingo syntax
put(member("First Names").text.line[3].word[1])

// JavaScript syntax
put(member("First Names").getPropRef("line", 1).getProp("word", 1));

[ ] (list)

Usage

[entry1, entry2, entry3, ...]

Description
List operator; specifies that the entries within the brackets are one of four types of lists:

- Unsorted linear lists
- Sorted linear lists
- Unsorted property lists
- Sorted property lists
Each entry in a linear list is a single value that has no other property associated with it. Each entry in a property list consists of a property and a value. The property appears before the value and is separated from the value by a colon. You cannot store a property in a linear list. When using strings as entries in a list, enclose the string in quotation marks.

For example, [6, 3, 8] is a linear list. The numbers have no properties associated with them. However, [#gears:6, #balls:3, #ramps:8] is a property list. Each number has a property—in this case, a type of machinery—associated with it. This property list could be useful for tracking the number of each type of machinery currently on the Stage in a mechanical simulation. Properties can appear more than once in a property list.

Lists can be sorted in alphanumeric order. A sorted linear list is ordered by the values in the list. A sorted property list is ordered by the properties in the list. You sort a list by using the appropriate command for a linear list or property list.

- In linear lists, symbols and strings are case sensitive.
- In property lists, symbols aren't case-sensitive, but strings are case-sensitive.

A linear list or property list can contain no values at all. An empty list consists of two square brackets ([]). To create or clear a linear list, set the list to [ ]. To create or clear a property list, set the list to [:].

You can modify, test, or read items in a list.

Lingo treats an instance of a list as a reference to the list. This means each instance is the same piece of data, and changing it will change the original. Use the duplicate command to create copies of lists.

Lists are automatically disposed when they are no longer referred to by any variable. When a list is held within a global variable, it persists from movie to movie.

You can initialize a list in the on prepareMovie handler or write the list as a field cast member, assign the list to a variable, and then handle the list by handling the variable.

Not all PC keyboards have square brackets. If square brackets aren't available, use the list function to create a linear list.

For a property list, create the list pieces as a string before converting them into a useful list.

```plaintext
myListString = numToChar(91) & ":" & numToChar(93)
put myListString
-- "[:"]
myList = myListString.value
put myList
-- [:]
put myList.listP
-- 1
myList["name"] = "Brynn"
put myList
-- ["name": "Brynn"]
```

Example

This statement defines a list by making the machinery variable equal to the list:

```plaintext
-- Lingo syntax
machinery = [#gears:6, #balls:3, #ramps:8]
// JavaScript syntax
var machinery = propList("gears",6, "balls",3, "ramps",8);
```
This handler sorts the list aList and then displays the result in the Message window:

```lingo
-- Lingo syntax
on sortList aList
    alist.sort()
    put(aList)
end sortList

// JavaScript syntax
function sortList(aList) {
    aList.sort();
    put(aList);
}
```

If the movie issues the statement `sortList machinery`, where `machinery` is the list in the preceding example, the result is `[#balls:3, #gears:6, #ramps:8]`.

The following statements create an empty linear list:

```lingo
-- Lingo syntax
x = [ ]
x = list()

// JavaScript syntax
var x = list();
```

The following statements create an empty property list:

```lingo
-- Lingo syntax
x = [:]
x = propList()

// JavaScript syntax
var x = propList();
```

`add, addVertex(), append, count(), deleteAt, duplicate() (list function), findPos, findPosNear, getProp(), getAt, getLast(), getPos(), ilk(), list(), max(), min, setAt, setaProp, sort`

@ (pathname)

**Usage**

`@pathReference`

**Description**

Pathname operator; defines the path to the current movie’s folder and is valid on both Windows and Macintosh computers.

Identify the current movie’s folder by using the @ symbol followed by one of these pathname separators:

- `/` (forward slash)
- `\` (backslash)
- `:` (colon)

When a movie is queried to determine its location, the string returned will include the `@` symbol.
Be sure to use only the @ symbol when navigating between Director movies or changing the source of a linked media cast member. The @ symbol does not work when the Fileio Xtra extension or other functions are used outside those available within Director.

You can build on this pathname to specify folders that are one or more levels above or below the current movie's folder. Keep in mind that the @ portion represents the current movie's location, not necessarily the location of the projector.

- Add an additional pathname separator immediately after the @ symbol to specify a folder one level up in the hierarchy.
- Add folder names and filenames (separated by /, \, or :) after the current folder name to specify subfolders and files within folders.

You can use relative pathnames in Lingo to indicate the location of a linked file in a folder different than the movie's folder.

**Example**

These are equivalent expressions that specify the subfolder bigFolder, which is in the current movie's folder:
- @/bigFolder
- @:bigFolder
- @\bigFolder

These are equivalent expressions that specify the file linkedFile, in the subfolder bigFolder, which is in the current movie's folder:
- @:bigFolder:linkedFile
- @\bigFolder\linkedFile
- @/bigFolder/linkedFile

This expression specifies the file linkedFile, which is located one level up from the current movie's folder:
- @//linkedFile

This expression specifies the file linkedFile, which is located two levels up from the current movie's folder:
- @:::linkedFile

These are equivalent expressions that specify the file linkedFile, which is in the folder otherFolder. The otherFolder folder is in the folder one level up from the current movie's folder.
- @::otherFolder:linkedFile
- @\otherFolder\linkedFile
- @/otherFolder/linkedFile

- fileName (Member)
- fileName (Window)
**and**

**Usage**

```-- Lingo syntax
logicalExpression1 and logicalExpression2
```

```// JavaScript syntax
logicalExpression1 && logicalExpression2
```

**Description**

Logical operator; determines whether both `logicalExpression1` and `logicalExpression2` are `TRUE` (1), or whether either or both expressions are `FALSE` (0).

The precedence level of this logical operator is 4.

**Example**

This statement determines whether both logical expressions are `TRUE` and displays the result in the Message window:

```-- Lingo syntax
put(1 < 2 and 2 < 3)
```

```// JavaScript syntax
put((1 < 2) && (2 < 3));
```

The result is 1, which is the numerical equivalent of `TRUE`.

The first logical expression in the following statement is `TRUE`; and the second logical expression is `FALSE`. Because both logical expressions are not `TRUE`, the logical operator displays the result 0, which is the numerical equivalent of `FALSE`.

```-- Lingo syntax
put(1 < 2 and 2 < 1)
```

```-- 0
```

```// JavaScript syntax
put((1 < 2) && (2 < 1));
```

```// 0```

**See also**

`not`, `or`

**contains**

**Usage**

```-- Lingo syntax
stringExpression1 contains stringExpression2
```

```// JavaScript syntax
stringExpression1.indexOf(stringExpression2);
```

**Description**

Operator; compares two strings and determines whether `stringExpression1` contains `stringExpression2` `TRUE` or `FALSE`.

The `contains` comparison operator has a precedence level of 1.
The `contains` comparison operator is useful for checking whether the user types a specific character or string of characters. You can also use the `contains` operator to search one or more fields for specific strings of characters.

**Example**

This example determines whether a character passed to it is a digit:

```-- Lingo syntax
on isNumber aLetter
digits = "1234567890"
if digits contains aLetter then
    return TRUE
else
    return FALSE
end if
end

// JavaScript syntax
function isNumber(aLetter) {
    var digits = "1234567890"
    if (digits.indexOf(aLetter) >= 0) {
        return true;
    } else {
        return false;
    }
}
```

*Note:* The string comparison is not sensitive to case or diacritical marks; “a” and Å are treated the same.

See also

`offset()` (string function), `starts`
// JavaScript syntax
put(7 % 4);

The result is 3.

The following handler sets the ink effect of all odd-numbered sprites to copy, which is the ink effect specified by the number 0. First the handler checks whether the sprite in the variable mySprite is an odd-numbered sprite by dividing the sprite number by 2 and then checking whether the remainder is 1. If the remainder is 1, the result for an odd-numbered number, the handler sets the ink effect to copy.

```
-- Lingo syntax
on setInk
    repeat with mySprite = 1 to _movie.lastChannel
        if (mySprite mod 2) = 1 then
            sprite(mySprite).ink = 0
        else
            sprite(mySprite).ink = 8
        end if
    end repeat
end setInk
```

This handler regularly cycles a sprite's cast member among a number of bitmaps:

```
-- Lingo syntax
on exitFrame
    global gCounter
    -- These are sample values for bitmap cast member numbers
    theBitmaps = [2,3,4,5,6,7]
    -- Specify which sprite channel is affected
    theChannel = 1
    -- This cycles through the list
    gCounter = 1 + (gCounter mod theBitmaps.count)
    sprite(theChannel).memberNum = theBitmaps[gCounter]
    _movie.go(_movie.frame)
end
```

// JavaScript syntax
function exitFrame() {
    // these are sample values for bitmap cast member numbers
    theBitmaps = new Array(2,3,4,5,6,7);
    // specify which sprite channel is affected
    theChannel = 1;
    // this cycles through the list
    _global.gCounter = 1 + (_global.gCounter % theBitmaps.length);
    sprite(theChannel).memberNum = theBitmaps[_global.gCounter];
    _movie.go(_movie.frame);
}
not

Usage
-- Lingo syntax
not logicalExpression

// JavaScript syntax
! logicalExpression

Description
Operator; performs a logical negation on a logical expression. This is the equivalent of making a TRUE value FALSE, and making a FALSE value TRUE. It is useful when testing to see if a certain known condition is not the case.

This logical operator has a precedence level of 5.

Example
This statement determines whether 1 is not less than 2:

-- Lingo syntax
put(not (1 < 2))

// JavaScript syntax
put(!(1 < 2));

Because 1 is less than 2, the result is 0, which indicates that the expression is FALSE.

This statement determines whether 1 is not greater than 2:

-- Lingo syntax
put(not (1 > 2))

// JavaScript syntax
put(!(1 > 2));

Because 1 is not greater than 2, the result is 1, which indicates that the expression is TRUE.

This handler sets the checkMark menu item property for Bold in the Style menu to the opposite of its current setting:

-- Lingo syntax
on resetMenuItem
  menu("Style").menuItem("Bold").checkMark = \
  not (menu("Style").menuItem("Bold").checkMark)
end resetMenuItem

// JavaScript syntax
function resetMenuItem() {
  menu("Style").menuItem("Bold").checkMark = \
  !(menu("Style").menuItem("Bold").checkMark)
}

See also
and, or
or

Usage

-- Lingo syntax
logicalExpression1 or logicalExpression2

// JavaScript syntax
logicalExpression1 || logicalExpression2

Description

Operator; performs a logical OR operation on two or more logical expressions to determine whether any expression is TRUE.

This is a logical operator with a precedence level of 4.

Example

This statement indicates in the Message window whether at least one of the expressions 1 < 2 and 1 > 2 is TRUE:

-- Lingo syntax
put((1 < 2) or (1 > 2))

// JavaScript syntax
put((1 < 2) || (1 > 2));

Because the first expression is TRUE, the result is 1, which is the numerical equivalent of TRUE.

This Lingo checks whether the content of the field cast member named State is either AK or HI and displays an alert if it is:

-- Lingo syntax
if member("State").text = "AK" or member("State").text = "HI" then
    _player.alert("You're off the map!")
end if

// JavaScript syntax
if (member("State").text == "AK" || member("State").text == "HI") {
    _player.alert("You're off the map!");
}

See also

and, not
starts

Usage

-- Lingo syntax
string1 starts string2

// JavaScript syntax
string1.indexOf(string2) == 0;

Description

Operator; compares to determines whether string1 starts with string2 (TRUE or 1) or not (FALSE or 0).

The string comparison is not sensitive to case or diacritical marks; a and Å are considered to be the same.

This is a comparison operator with a precedence level of 1.

Example

This statement reports in the Message window whether the word Macromedia starts with the string “Macro”:

-- Lingo syntax
put("Macromedia" starts "Macro")

// JavaScript syntax
var string1 = "Macromedia";
put(string1.indexOf("Macro") == 0);

The result is 1, which is the numerical equivalent of TRUE.

contains
This section provides an alphabetical list of all the properties available in Macromedia Director MX 2004.

_global

Usage
-- Lingo syntax
_global

// JavaScript syntax
_global;

Description
Top-level property; provides a reference to the Global object, which stores all global variables. Read-only.
All global variables are accessible to both Lingo and JavaScript syntax.

Example
This statement sets the variable objGlobal to the _global property:
-- Lingo syntax
objGlobal = _global

// JavaScript syntax
var objGlobal = _global;

This statement uses the _global property directly to clear all global variables:
-- Lingo syntax
_global.clearGlobals()

// JavaScript syntax
_global.clearGlobals();

See also
Global
_key

Usage
-- Lingo syntax
_key

// JavaScript syntax
_key;

Description
Top-level property; provides a reference to the Key object, which is used to monitor a user's keyboard activity. Read-only.

Example
This statement sets the variable objKey to the _key property:
-- Lingo syntax
objKey = _key

// JavaScript syntax
var objKey = _key;

This statement uses the _key property directly to access the value of the key property:
-- Lingo syntax
theKey = _key.key

// JavaScript syntax
var theKey = _key.key;

See also
Key

_mouse

Usage
-- Lingo syntax
_mouse

// JavaScript syntax
_mouse;

Description
Top-level property; provides a reference to the Mouse object, which provides access to a user's mouse activity, including mouse movement and mouse clicks. Read-only.

Example
This statement sets the variable objMouse to the _mouse property:
-- Lingo syntax
objMouse = _mouse

// JavaScript syntax
var objMouse = _mouse;
This statement uses the \_mouse property directly to access the value of the \_mouseH property:

-- Lingo syntax
theMouseH = \_mouse.mouseH

// JavaScript syntax
var theMouseH = \_mouse.mouseH;

See also
Mouse

\_movie

Usage

-- Lingo syntax
\_movie

// JavaScript syntax
\_movie;

Description

Top-level property; provides a reference to the Movie object, which represents the currently active movie within the Director player, and provides access to properties and methods that are available on a movie level. Read-only.

Example

This statement sets the variable objMovie to the \_movie property:

-- Lingo syntax
objMovie = \_movie

// JavaScript syntax
var objMovie = \_movie;

This statement uses the \_movie property directly to access the value of the displayTemplate property:

-- Lingo syntax
theTemplate = \_movie.displayTemplate

// JavaScript syntax
var theTemplate = \_movie.displayTemplate;

See also
Movie
_player

Usage
-- Lingo syntax
_player

// JavaScript syntax
_player;

Description
Top-level property; provides a reference to the Player object, which manages and executes all movies, including movies in a window (MIAWs). Read-only.

Example
This statement sets the variable objPlayer to the _player property:

-- Lingo syntax
objPlayer = _player

// JavaScript syntax
var objPlayer = _player;

This statement uses the _player property directly to access the value of the xtraList property:

-- Lingo syntax
theXtras = _player.xtraList

// JavaScript syntax
var theXtras = _player.xtraList;

See also
Player

_sound

Usage
-- Lingo syntax
_sound

// JavaScript syntax
_sound;

Description
Top-level property; provides a reference to the Sound object, which controls audio playback in all eight available sound channels. Read-only.

Example
This statement sets the variable objSound to the _sound property:

-- Lingo syntax
objSound = _sound

// JavaScript syntax
var objSound = _sound;
This statement uses the _sound property directly to access the soundLevel property:

-- Lingo syntax
theLevel = _sound.soundLevel

// JavaScript syntax
var theLevel = _sound.soundLevel;

See also
Sound

_system

Usage

-- Lingo syntax
_system

// JavaScript syntax
_system;

Description

Top-level property; provides a reference to the System object, which provides access to system and environment information, including system level methods. Read-only.

Example

This statement sets the variable objSystem to the _system property:

-- Lingo syntax
objSystem = _system

// JavaScript syntax
var objSystem = _system;

This statement uses the _system property directly to access the freeBytes property:

-- Lingo syntax
theBytes = _system.freeBytes

// JavaScript syntax
var theBytes = _system.freeBytes;

See also
System

aboutInfo

Usage

-- Lingo syntax
_movie.aboutInfo

// JavaScript syntax
_movie.aboutInfo;

Description

Movie property; a string entered during authoring in the Movie Properties dialog box. Read-only.
Example

These statements display movie information in the Message window.

-- Lingo syntax
trace(_movie.aboutInfo)

// JavaScript syntax
trace(_movie.aboutInfo);

See also
copyrightInfo (Movie), Movie

actionsEnabled

Usage

-- Lingo syntax
memberOrSpriteObjRef.actionsEnabled

// JavaScript syntax
memberOrSpriteObjRef.actionsEnabled;

Description

Cast member property and sprite property; controls whether the actions in Macromedia Flash content are enabled (TRUE, default) or disabled (FALSE).

This property can be tested and set.

Example

This handler accepts a sprite reference as a parameter, and then toggles the sprite’s actionsEnabled property on or off.

-- Lingo syntax
on ToggleActions(whichSprite)
    sprite(whichSprite).actionsEnabled = \not(sprite(whichSprite).actionsEnabled)
end

// JavaScript syntax
function ToggleActions(whichSprite) {
    switch(sprite(whichSprite).actionsEnabled) {
        case 0:
            sprite(whichSprite).actionsEnabled = 1;
            break;
        case 1:
            sprite(whichSprite).actionsEnabled = 0;
            break;
    }
}
**active3dRenderer**

**Usage**

-- Lingo syntax
_movie.active3dRenderer

// JavaScript syntax
_movie.active3dRenderer;

**Description**

Movie property; Indicates the renderer currently in use by the movie for drawing 3D sprites. This property is equivalent to the `getRendererServices().renderer` property. Read-only.

The possible values of the `active3dRenderer` property are `#openGL`, `#directX7_0`, `#directX5_2`, and `#software`. The values `#openGL`, `#directX7_0`, and `#directX5_2`, which are video card drivers, will lead to much faster performance than `#software`, a software renderer used when none of the first three options are available.

Use `getRendererServices().renderer` to set this property.

**Example**

These examples show the two ways to determine which renderer is currently in use.

-- Lingo syntax
put(_movie.active3dRenderer)
put(getRendererServices().renderer)

// JavaScript syntax
put(_movie.active3dRenderer);
put(getRendererServices().renderer);

**See also**

`Movie`, `renderer`

---

**activeCastLib**

**Usage**

-- Lingo syntax
_player.activeCastLib

// JavaScript syntax
_player.activeCastLib;

**Description**

Player property; indicates which cast library was most recently activated. Read-only.

The `activeCastLib` property's value is the cast library's number.

The `activeCastLib` property is useful when working with the Cast object's `selection` property. Use it to determine which cast library the selection refers to.
Example

These statements assign the selected cast members in the most recently selected cast to the variable selectedMembers:

--- Lingo syntax
castLibOfInterest = _player.activeCastLib
selectedMembers = castLib(castLibOfInterest).selection

// JavaScript syntax
var castLibOfInterest = _player.activeCastLib;
var selectedMembers = castLib(castLibOfInterest).selection;

See also  
Player, selection

activeWindow

Usage

--- Lingo syntax
_player.activeWindow

// JavaScript syntax
_player.activeWindow:

Description

Player property; indicates which movie window is currently active. Read-only.

For the main movie, activeWindow is the Stage. For a movie in a window (MIAW), activeWindow is the movie in the window.

Example

This example places the word Active in the title bar of the clicked window and places the word Inactive in the title bar of all other open windows:

--- Lingo syntax
on activateWindow
  clickedWindow = _player.windowList.getPos(_player.activeWindow)
  windowCount = _player.windowList.count
  repeat with x = 1 to windowCount
    if (x = clickedWindow) then
      _player.window[clickedWindow].title = "Active"
    else
      _player.windowList[x].title = "Inactive"
    end if
  end repeat
end activateWindow

// JavaScript syntax
function activateWindow() {
  var clickedWindow = _player.windowList.getPos(_player.activeWindow);
  var windowCount = _player.windowList.count;
  for (var x = 1; x <= windowCount; x++) {
    if (x == clickedWindow) {
      _player.window[clickedWindow].title = "Active"
    } else {
      _player.windowList[x].title = "Inactive"
    }
  }
}

620  Chapter 14: Properties
**actorList**

**Usage**

```-- Lingo syntax
_movie.actorList
```

```// JavaScript syntax
_movie.actorList;
```

**Description**

Movie property; a list of child objects that have been explicitly added to this list. Read/write.

Objects in `actorList` receive a `stepFrame` message each time the playhead enters a frame.

To add an object to the `actorList`, use `_movie.actorList.append(newScriptObjRef)`. The object’s `stepFrame` handler in its parent or ancestor script will then be called automatically at each frame advance.

To clear objects from the `actorList`, set `actorList` to `[ ]`, which is an empty list.

Director doesn’t clear the contents of `actorList` when branching to another movie, which can cause unpredictable behavior in the new movie. To prevent child objects in the current movie from being carried over to the new movie, insert the statement `actorList = [ ]` in the `prepareMovie` handler of the new movie.

**Example**

This statement adds a child object created from the parent script Moving Ball. All three values are parameters that the script requires.

This statement displays the contents of `actorList` in the Message window:

```-- Lingo syntax
put(_movie.actorList)
```

```// JavaScript syntax
put(_movie.actorList);
```

This statement clears objects from `actorList`.

```-- Lingo syntax
_movie.actorList = [] -- using brackets
_movie.actorList = list() -- using list()
```

```// JavaScript syntax
_movie.actorList = list();
```

**See also**

`Movie`, `on prepareMovie`, `on stepFrame`
alertHook

Usage

-- Lingo syntax
_player.alertHook

// JavaScript syntax
_player.alertHook;

Description

Player property; specifies a parent script that contains the alertHook handler. Read/write.

Use alertHook to control the display of alerts about file errors or script errors. When an error occurs and a parent script is assigned to alertHook, Director runs the alertHook handler in the parent script.

Although it is possible to place alertHook handlers in movie scripts, it is strongly recommended that you place an alertHook handler in a behavior or parent script to avoid unintentionally calling the handler from a wide variety of locations and creating confusion about where the error occurred.

Because the alertHook handler runs when an error occurs, avoid using the alertHook handler for script that isn’t involved in handling an error. For example, the alertHook handler is a bad location for a go() statement.

The alertHook handler is passed an instance argument, two string arguments that describe the error, and an optional argument specifying an additional event that invokes the handler.

The fourth argument can have 1 of these 4 values:

• #alert—causes the handler to be triggered by the alert() method.
• #movie—causes the handler to be triggered by a file not found error while performing a go() command.
• #script—causes the handler to be triggered by a script error.
• #safeplayer—causes the handler to be triggered by a check of the safePlayer property.

Depending on the script within it, the alertHook handler can ignore the error or report it in another way.

Example

The following statement specifies that the parent script Alert is the script that determines whether to display alerts when an error occurs. If an error occurs, the script assigns the error and message strings to the field cast member Output and returns the value 1.

-- Lingo syntax
on prepareMovie
_player.alertHook = script("Alert")
end

-- "Alert" script
on alertHook me, err, msg
    member("Output").text = err && msg
    return 1
end
// JavaScript syntax
function prepareMovie() {
    _player.alertHook = alert("Error type", "Error message");
}

// alert handler
function alert(err, msg) {
    member("Output").text = err + " " + msg;
    return 1;
}

See also
alertHook, Player, safePlayer

alignment

Usage

-- Lingo syntax
memberObjRef.alignment

// JavaScript syntax
memberObjRef.alignment;

Description

Cast member property; determines the alignment used to display characters within the specified cast member. This property appears only to field and text cast members containing characters, if only a space.

For field cast members, the value of the property is a string consisting of one of the following: left, center, or right.

For text cast members, the value of the property is a symbol consisting of one of the following: #left, #center, #right, or #full.

The parameter whichCastMember can be either a cast name or a cast number.

This property can be tested and set. For text cast members, the property can be set on a per-paragraph basis.

Example

This statement sets the variable named characterAlign to the current alignment setting for the field cast member Rokujo Speaks:

--Lingo syntax
characterAlign = member("Rokujo Speaks").alignment

// JavaScript syntax
var characterAlign = member("Rokujo Speaks").alignment;

See also
text, font, lineHeight, fontSize, fontStyle, &. + (concatenation operator), &&, + (concatenation operator)
allowCustomCaching

Usage

-- Lingo syntax
_movie.allowCustomCaching

// JavaScript syntax
_movie.allowCustomCaching;

Description

Movie property; will contain information regarding a private cache in future versions of Director.
Read/write.

This property defaults to TRUE.

See also

allowGraphicMenu, allowSaveLocal, allowTransportControl, allowVolumeControl, allowZooming, Movie

allowGraphicMenu

Usage

-- Lingo syntax
_movie.allowGraphicMenu

// JavaScript syntax
_movie.allowGraphicMenu;

Description

Movie property; sets the availability of the graphic controls in the context menu when playing the
movie in a Macromedia Shockwave environment. Read/write.

Set this property to FALSE if you would rather have a text menu displayed than the graphic
context menu.

This property defaults to TRUE.

See also

allowCustomCaching, allowSaveLocal, allowTransportControl, allowVolumeControl, allowZooming, Movie

allowSaveLocal

Usage

-- Lingo syntax
_movie.allowSaveLocal

// JavaScript syntax
_movie.allowSaveLocal;

Description

Movie property; sets the availability of the Save control in the context menu when playing the
movie in a Shockwave Player environment. Read/write.

This property is provided to allow for enhancements in future versions of Shockwave Player.
This property defaults to TRUE.

See also
allowCustomCaching, allowGraphicMenu, allowTransportControl,
allowVolumeControl, allowZooming, Movie

allowTransportControl

Usage
-- Lingo syntax
_movie.allowTransportControl

// JavaScript syntax
_movie.allowTransportControl;

Description
Movie property; this property is provided to allow for enhancements in future versions of Shockwave Player. Read/write.

This property defaults to TRUE.

See also
allowCustomCaching, allowGraphicMenu, allowSaveLocal, allowVolumeControl,
allowZooming, Movie

allowVolumeControl

Usage
-- Lingo syntax
_movie.allowVolumeControl

// JavaScript syntax
_movie.allowVolumeControl;

Description
Movie property; sets the availability of the volume control in the context menu when playing the movie in a Shockwave Player environment. Read/write.

When set to TRUE one or the other volume control is active, and is disabled when the property is set to FALSE.

This property defaults to TRUE.

See also
allowCustomCaching, allowGraphicMenu, allowSaveLocal, allowTransportControl,
allowZooming, Movie
allowZooming

Usage

-- Lingo syntax
_movie.allowZooming

// JavaScript syntax
_movie.allowZooming;

Description

Movie property; determines whether the movie may be stretched or zoomed by the user when playing back in Shockwave Player and ShockMachine. Read/write.

Set this property to FALSE to prevent users from changing the size of the movie in browsers and ShockMachine.

The property defaults to TRUE.

See also

allowCustomCaching, allowGraphicMenu, allowSaveLocal, allowTransportControl, allowVolumeControl, Movie

alphaThreshold

Usage

-- Lingo syntax
memberObjRef.alphaThreshold

// JavaScript syntax
memberObjRef.alphaThreshold;

Description

Bitmap cast member property; governs how the bitmap's alpha channel affects hit detection. This property is a value from 0 to 255, that exactly matches alpha values in the alpha channel for a 32-bit bitmap image.

For a given alphaThreshold setting, Director detects a mouse click if the pixel value of the alpha map at that point is equal to or greater than the threshold. Setting the alphaThreshold to 0 makes all pixels opaque to hit detection regardless of the contents of the alpha channel.

See also

useAlpha

ambient

Usage

member(whichCastmember).shader(whichShader).ambient
member(whichCastmember).model(whichModel).shader.ambient
member(whichCastmember).model(whichModel).shaderList[[index]].\ambient

Description

3D #standard shader property; indicates how much of each color component of the ambient light in the cast member is reflected by the shader.
For example, if the color of the ambient light is rgb(255, 255, 255) and the value of the ambient property of the shader is rgb(255, 0, 0), the shader will reflect all of the red component of the light that the shader's colors can reflect. However, it will reflect none of the blue and green components of the light, regardless of the colors of the shader. In this case, if there are no other lights in the scene, the blue and green colors of the shader will reflect no light, and will appear black.

The default value of this property is rgb(63, 63, 63).

**Example**

This statement sets the ambient property of the model named Chair to rgb(255, 255, 0). Chair will fully reflect the red and green components of the ambient light in the scene and completely ignore its blue component.

```plaintext
member("Room").model("Chair").shader.ambient = rgb(255, 0, 0)
```

**See also**

ambientColor, newLight, type (light), diffuse, specular (shader)

### ambientColor

**Usage**

```plaintext
member(whichCastmember).ambientColor
```

**Description**

3D cast member property; indicates the RGB color of the default ambient light of the cast member.

The default value for this property is rgb(0, 0, 0). This adds no light to the scene.

**Example**

This statement sets the ambientColor property of the cast member named Room to rgb(255, 0, 0). The default ambient light of the cast member will be red. This property can also be set in the Property inspector.

```plaintext
member("Room").ambientColor = rgb(255, 0, 0)
```

**See also**

directionalColor, directionalPreset, ambient

### ancestor

**Usage**

```plaintext
property {optionalProperties} ancestor
```

**Description**

Object property; allows child objects and behaviors to use handlers that are not contained within the parent script or behavior.

The ancestor property is typically used with two or more parent scripts. You can use this property when you want child objects and behaviors to share certain behaviors that are inherited from an ancestor, while differing in other behaviors that are inherited from the parents.
For child objects, the **ancestor** property is usually assigned in the **on new** handler within the parent script. Sending a message to a child object that does not have a defined handler forwards that message to the script defined by the **ancestor** property.

If a behavior has an ancestor, the ancestor receives mouse events such as **mouseDown** and **mouseWithin**.

The **ancestor** property lets you change behaviors and properties for a large group of objects with a single command.

The ancestor script can contain independent property variables that can be obtained by child objects. To refer to property variables within the ancestor script, you must use this syntax:

```
me.propertyVariable = value
```

For example, this statement changes the property variable `legCount` within an ancestor script to 4:

```
me.legCount = 4
```

Use the syntax `the variableName of scriptName` to access property variables that are not contained within the current object. This statement allows the variable `myLegCount` within the child object to access the property variable `legCount` within the ancestor script:

```
set myLegCount to the legCount of me
```

**Example**

Each of the following scripts is a cast member. The ancestor script Animal and the parent scripts Dog and Man interact with one another to define objects.

The first script, Dog, sets the property variable **breed** to Mutt, sets the **ancestor** of Dog to the Animal script, and sets the **legCount** variable that is stored in the ancestor script to 4:

```plaintext
property breed, ancestor
on new me
    set breed = "Mutt"
    set the ancestor of me to new(script "Animal")
    set the legCount of me to 4
    return me
end
```

The second script, Man, sets the property variable **race** to Caucasian, sets the **ancestor** of Man to the Animal script, and sets the **legCount** variable that is stored in the ancestor script to 2:

```plaintext
property race, ancestor
on new me
    set race to "Caucasian"
    set the ancestor of me to new(script "Animal")
    set the legCount of me to 2
    return me
end
```

**See also**

`new()`, `me`, `property`
**angle (3D)**

**Usage**

```lingo
member(whichCastmember).modelResource(whichModelResource).\emitter.angle
```

**Description**

3D emitter property; describes the area into which the particles of a particle system are emitted. A particle system is a model resource whose type is `#particle`.

The primary direction of particle emission is the vector set by the emitter's `direction` property. However, the direction of emission of a given particle will deviate from that vector by a random angle between 0 and the value of the emitter's `angle` property.

The effective range of this property is 0.0 to 180.0. The default value is 180.0.

**Example**

This statement sets the angle of emission of the model resource named `mrFount` to 1, which causes the emitted particles to form a thin line.

```lingo
member("fountain").modelResource("mrFount").emitter.angle = 1
```

**See also**

`emitter`, `direction`

---

**angle (DVD)**

**Usage**

```lingo
-- Lingo syntax
dvdObjRef.angle

// JavaScript syntax
dvdObjRef.angle;
```

**Description**

DVD property; returns the number of the current camera angle. Read-only.

The returned number is an integer.

**Example**

This statement returns the number of the current camera angles:

```lingo
-- Lingo syntax
put(sprite(12).angle)

// JavaScript syntax
put(sprite(12).angle);
```

**See also**

`DVD`
angleCount

Usage
-- Lingo syntax
dvdObjRef.angleCount

// JavaScript syntax
dvdObjRef.angleCount;

Description
DVD property; returns the number of available camera angles in the current title. Read-only.
The returned value is an integer that can range from 1 to 9.

Example
This statement returns the number of available camera angles:
-- Lingo syntax
put(member(12).angleCount)

// JavaScript syntax
put(member(12).angleCount);

See also
DVD

animationEnabled

Usage
member(whichCastmember).animationEnabled

Description
3D cast member property; indicates whether motions will be executed (TRUE) or ignored (FALSE).
This property can also be set in the Property inspector.
The default value for this property is TRUE.

Example
This statement disables animation for the cast member named Scene.
member("Scene").animationEnabled = FALSE

antiAlias

Usage
-- Lingo syntax
memberOrSpriteObjRef.antiAlias

// JavaScript syntax
memberOrSpriteObjRef.antiAlias;
Description

Cast member property; controls whether a text, Vector shape, or Flash cast member is rendered using anti-aliasing to produce high-quality rendering, but possibly slower playback of the movie. The antiAlias property is TRUE by default.

For vector shapes, TRUE is the equivalent of the #high quality setting for a Flash asset, and FALSE is the equivalent of #low.

The antiAlias property may also be used as a sprite property only for Vector shape sprites.

This property can be tested and set.

Example

This behavior checks the color depth of the computer on which the movie is playing. If the color depth is set to 8 bits or less (256 colors), the script sets the antiAlias property of the sprite to FALSE.

--Lingo syntax
property spriteNum

on beginsprite me
  if _system.colorDepth <= 8 then
    sprite(spriteNum).antiAlias = FALSE
  end if
end

// JavaScript syntax
function beginsprite() {
  var cd = _system.colorDepth;
  if (cd <= 8) {
    sprite(this.spriteNum).antiAlias = 0;
  }
}

See also

antiAliasThreshold, quality

antiAliasingEnabled

Usage

sprite(whichSprite).antiAliasingEnabled

Description

3D sprite property; indicates whether the 3D world in the sprite whichSprite is anti-aliased. It can be tested and set. The default value is FALSE, indicating that anti-aliasing is off. If the antiAliasingEnabled property is set to TRUE and the 3D renderer changes to a renderer that does not support anti-aliasing, the property is set to FALSE. The value of this property is not saved when the movie is saved.

Anti-aliased sprites use more processor power and memory than sprites that are not anti-aliased. Temporarily turning off anti-aliasing can improve the performance of animations and user interaction.
Example

This Lingo checks whether the currently running 3D renderer for sprite 2 supports anti-aliasing with the `antiAliasingSupported` property. If anti-aliasing is supported, the second statement turns on anti-aliasing for the sprite with the `antiAliasingEnabled` property.

```lingo
if sprite(2).antiAliasingSupported = TRUE then
    sprite(2).antiAliasingEnabled = TRUE
end if
```

See also `antiAliasingSupported, renderer, rendererDeviceList`

antiAliasingSupported

Usage

```lingo
sprite(whichSprite).antiAliasingSupported
```

Description

3D sprite property; indicates whether anti-aliasing is supported by the current 3D renderer. This property can be tested but not set. This property returns either `TRUE` or `FALSE`.

Example

This Lingo checks whether the currently running 3D renderer for sprite 3 supports anti-aliasing. If anti-aliasing is supported, the second statement turns on anti-aliasing for the sprite with the `antiAliasingEnabled` property.

```lingo
if sprite(3).antiAliasingSupported = TRUE then
    sprite(3).antiAliasingEnabled = TRUE
end if
```

See also `antiAliasingEnabled, renderer, rendererDeviceList`

antiAliasThreshold

Usage

```lingo
-- Lingo syntax
memberObjRef.antiAliasThreshold

// JavaScript syntax
memberObjRef.antiAliasThreshold;
```

Description

Text cast member property; this setting controls the point size at which automatic anti-aliasing takes place in a text cast member. This has an effect only when the `antiAlias` property of the text cast member is set to `TRUE`.

The setting itself is an integer indicating the font point size at which the anti-alias takes place. This property defaults to 14 points.

See also `antiAlias`
appearanceOptions

Usage

**-- Lingo syntax**

`windowObjRef.appearanceOptions`

```javascript
// JavaScript syntax
windowObjRef.appearanceOptions;
```

**Description**

Window property; specifies a list of properties that stores the appearance options of a window. Read/write.

The property list contains the following properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#mask</td>
<td>Specifies the 1-bit cast member to use as a mask for the window.</td>
</tr>
</tbody>
</table>
| #border   | Specifies the type of border for the window. This property can be one of three values:  
  • #none. Specifies no border around the window.  
  • #line. Specifies a 1-pixel black border around the window.  
  The #none and #line properties are only effective if the `titlebarOptions.visible` property is set to FALSE. |
| #metal    | (Macintosh only) Specifies whether the window should have a metal look (TRUE). If FALSE, the window will have an ice look. |
| #dragRegionMask | Specifies the 1-bit cast member to use as a mask for a region of the window. |
| #shadow   | (Macintosh only) Specifies whether the window should have a shadow.  
  Macintosh windows typically have a shadow. |
| #liveresize | (Macintosh only) Specifies whether the window should have live resizing. If TRUE, live resizing is enabled. If FALSE, live resizing is disabled. |

These properties can also be accessed by using the Movie object’s `displayTemplate` property.

**Example**

This statement displays in the Message window all current appearance options for the window named Control Panel:

**-- Lingo syntax**

`put(window("Control Panel").appearanceOptions)`

```javascript
// JavaScript syntax
put(window("Control Panel").appearanceOptions);
```

This statement sets the border property to display a 1-pixel border around the window named Control Panel:

**-- Lingo syntax**

`window("Control Panel").appearanceOptions.border = #line`

```javascript
// JavaScript syntax
window("Control Panel").appearanceOptions.border = "line";
```

**See also**

`displayTemplate, titlebarOptions, visible, Window`
**applicationName**

**Usage**

-- Lingo syntax
_player.applicationName

// JavaScript syntax
_player.applicationName;

**Description**

Player property; specifies the name of the running copy of the Director application during authoring, or the name of a projector file during runtime. Read-only.

The property value is a string.

Shockwave Player does not support this property.

**Example**

This statement displays the name of the Director application, Director.exe.

-- Lingo syntax
put(_player.applicationName)

// JavaScript syntax
put(_player.applicationName);

**See also**

applicationPath, Player

**applicationPath**

**Usage**

-- Lingo syntax
_player.applicationPath

// JavaScript syntax
_player.applicationPath;

**Description**

Player property; determines the path or location of the folder containing the running copy of the Director application during authoring, or the folder containing the projector during runtime. Read-only.

The property value is a string.

If you use applicationPath followed by & and a path to a subfolder, enclose the entire expression in parentheses so that script parses the expression as one phrase.

Shockwave Player does not support this property.

**Example**

This statement displays the pathname for the folder that contains the Director application.

-- Lingo syntax
put(_player.applicationPath)
attenuation

Usage

```-- Lingo syntax
member(whichCastMember).light(whichLight).attenuation
```

Description

3D light property; indicates the constant, linear, and quadratic attenuation factors for spotlights and point lights.

The default value for this property is vector(1.0, 0.0, 0.0).
Example

This statement sets the `attenuation` property of the light named `HouseLight` to the vector `(5, 0, 0), darkening it slightly.

```
member("3d world").light("HouseLight").attenuation = \n  vector(.5, 0, 0)
```

**See also**

color (light)

attributeName

**Usage**

`XMLnode.attributeName[ attributeNumber ]`

**Description**

XML property; returns the name of the specified child node of a parsed XML document.

**Example**

Beginning with the following XML:

```
<?xml version="1.0"?>
<e1>
  <tagName attr1="val1" attr2="val2"/>
  <e2>element 2</e2>
  <e3>element 3</e3>
  here is some text
</e1>
```

- This Lingo returns the name of the first attribute of the tag called `tagName`:
  put gParserObject.child[1].child[1].attributeName[1] -- "attr1"

**See also**

attributeValue

attributeValue

**Usage**

`XMLnode.attributeValue[ attributeNameOrNumber ]`

**Description**

XML property; returns the value of the specified child node of a parsed XML document.

**Example**

Beginning with the following XML:

```
<?xml version="1.0"?>
<e1>
  <tagName attr1="val1" attr2="val2"/>
  <e2>element 2</e2>
  <e3>element 3</e3>
  here is some text
</e1>
```
This Lingo returns the value of the first attribute of the tag called *tagName*:

```
put gParserObject.child[1].child[1].attributeValue[1]
-- "val1"
```

See also

`attributeName`

### audio (DVD)

**Usage**

- **Lingo syntax**
  
  `dvdObjRef.audio`
  
  // JavaScript syntax
  
  `dvdObjRef.audio;`

**Description**

DVD property. Determines whether audio is enabled (*TRUE*, default) or not (*FALSE*). Read/write.

**Example**

This statement disables audio:

- **Lingo syntax**
  
  `member(14).audio = 0`
  
  // JavaScript syntax
  
  `member(14).audio = 0;`

See also

`DVD`

### audio (RealMedia)

**Usage**

- **Lingo syntax**
  
  `memberOrSpriteObjRef.audio`
  
  // JavaScript syntax
  
  `memberOrSpriteObjRef.audio;`

**Description**

RealMedia sprite or cast member property; allows you to play (*TRUE*) or mute (*FALSE*) the audio in the RealMedia stream. The default setting for this property is *TRUE* (1). Integer values other than 1 or 0 are treated as *TRUE* (1). Setting this property has no effect if the `realPlayerNativeAudio()` method is set to *TRUE*.

If the *audio* property is set to *FALSE* when a RealMedia cast member starts playing, a sound channel is still allocated, which allows you to toggle the sound on and off during playback.

There may be some latency involved in setting this property, which means there may be a slight delay before the sound toggles on or off.
Example

The following examples show that the `audio` properties for sprite 2 and the cast member Real is set to `TRUE`, which means that the audio portion of the RealMedia stream will be played.

```lingo
-- Lingo syntax
put(sprite(2).audio) -- 1
put(member("Real").audio) -- 1
```

```javascript
// JavaScript syntax
put(sprite(2).audio); // 1
put(member("Real").audio); // 1
```

The following Lingo sets the `audio` property for sprite 2 and the cast member Real to `FALSE`, which means that the audio portion of the RealMedia stream will not be played when the movie is played.

```lingo
-- Lingo syntax
sprite(2).audio = FALSE
member("Real").audio = FALSE
```

```javascript
// JavaScript syntax
sprite(2).audio = 0;
member("Real").audio = 0;
```

See also

`soundChannel (RealMedia), video (RealMedia, Windows Media), sound (Player)`

### audio (Windows Media)

#### Usage

```lingo
-- Lingo syntax
windowsMediaObjRef.audio
```

```javascript
// JavaScript syntax
windowsMediaObjRef.audio;
```

#### Description

Windows Media property. Specifies whether audio is enabled (`TRUE`, default) or not (`FALSE`) during playback. Read/write.

#### Example

This statement displays in the Message window whether audio is enabled for cast member 5:

```lingo
-- Lingo syntax
trace(member(5).audio)
```

```javascript
// JavaScript syntax
trace(member(5).audio);
```

See also

`Windows Media`
### audioChannelCount

**Usage**

-- Lingo syntax
dvdObjRef.audioChannelCount

// JavaScript syntax
dvdObjRef.audioChannelCount;

**Description**
DVD property; returns the number of audio channels. Read-only.

**See also**
DVD

### audioExtension

**Usage**

-- Lingo syntax
dvdObjRef.audioExtension

// JavaScript syntax
dvdObjRef.audioExtension;

**Description**
DVD property. Returns a symbol that indicates the audio language extensions, if any, of an audio stream. Read-only.

Possible returned values are as follows:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#caption</td>
<td>The audio stream contains captions.</td>
</tr>
<tr>
<td>#lowvision</td>
<td>The audio stream contains content for people with low vision.</td>
</tr>
<tr>
<td>#directorcomments1</td>
<td>The audio stream contains &quot;director comments 1.&quot;</td>
</tr>
<tr>
<td>#directorcomments2</td>
<td>The audio stream contains &quot;director comments 2.&quot;</td>
</tr>
<tr>
<td>#none</td>
<td>The DVD does not specify an audio language extension for this audio stream, or it could not be determined.</td>
</tr>
</tbody>
</table>

**See also**
DVD
audioFormat

Usage

-- Lingo syntax
dvdObjRef.audioFormat

JavaScript syntax
dvdObjRef.audioFormat;

Description

DVD property. Returns a symbol that indicates the format (encoding mode) of an audio stream. Read-only.

Possible returned values are as follows:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#AC3</td>
<td>The audio format is Dolby AC-3.</td>
</tr>
<tr>
<td>#MPEG1</td>
<td>The audio format is MPEG-1.</td>
</tr>
<tr>
<td>#MPEG1DRC</td>
<td>The audio format is MPEG-1 with dynamic range control.</td>
</tr>
<tr>
<td>#MPEG2</td>
<td>The audio format is MPEG-2.</td>
</tr>
<tr>
<td>#MPEG2DRC</td>
<td>The audio format is MPEG-2 with dynamic range control</td>
</tr>
<tr>
<td>#LPCM</td>
<td>The audio format is Linear Pulse Code Modulated (LPCM).</td>
</tr>
<tr>
<td>#DTS</td>
<td>The audio format is Digital Theater Systems (DTS).</td>
</tr>
<tr>
<td>#SDDS</td>
<td>The audio format is Sony Dynamic Digital Sound (SDDS).</td>
</tr>
</tbody>
</table>

See also

DVD

audioSampleRate

Usage

-- Lingo syntax
dvdObjRef.audioSampleRate

JavaScript syntax
dvdObjRef.audioSampleRate;

Description

DVD property; returns the frequency, in hertz, of an audio stream. Read-only.

See also

DVD
audioStream

Usage
--- Lingo syntax
dvdObjRef.audioStream

// JavaScript syntax
dvdObjRef.audioStream;

Description
DVD property. Returns the currently active audio stream. Read/write.
Valid values range from 1 to 8.

See also
DVD

audioStreamCount

Usage
--- Lingo syntax
dvdObjRef.audioStreamCount

// JavaScript syntax
dvdObjRef.audioStreamCount;

Description
DVD property; returns the number of available audio streams in the current title. Read-only.
The number of available audio streams ranges from 1 to 8.

See also
DVD

auto

Usage
member(whichCastmember).model(whichModel).lod.auto

Description
3D lod modifier property; allows the modifier to manage the reduction of detail in the model as
the distance between the model and the camera changes.
The setting of the modifier's bias property determines how aggressively the modifier removes
detail from the model when the auto property is set to TRUE.
The modifier updates its level property as it adjusts the model's level of detail. Setting the level
property has no effect unless the auto property is set to FALSE.
The #lod modifier can only be added to models created outside of Director in 3D modeling
programs. The value of the type property of the model resources used by these models is
#fromFile. The modifier cannot be added to primitives created within Director.
Example

This statement sets the auto property of the lod modifier of the model named Spaceship to TRUE. The modifier will automatically set the model’s level of detail.

```
member("3D World").model("Spaceship").lod.auto = TRUE
```

See also

lod (modifier), bias, level

autoblend

Usage

```
member(whichCastmember).model(whichModel).
    keyframePlayer.autoblend
member(whichCastmember).model(whichModel).bonesPlayer.autoblend
```

Description

3D keyframePlayer and bonesPlayer modifier property; indicates whether the modifier creates a linear transition to the currently playing motion from the motion that preceded it (TRUE) or not (FALSE). If autoBlend is TRUE, the length of the transition is set by the blendTime property of the modifier. If autoBlend is FALSE, the transition is controlled by the blendFactor property of the modifier and blendTime is ignored.

Motion blending is completely disabled when blendTime is set to 0 and autoBlend is set to TRUE.

The default value of this property is TRUE.

Example

This statement turns autoblend off for the model named Alien3. The model’s blendFactor setting will be used for blending successive motions in the playlist.

```
member("newaliens").model("Alien3").keyframePlayer.
    autoblend = FALSE
```

See also

blendFactor, blendTime

autoCameraPosition

Usage

```
member(whichTextCastmember).autoCameraPosition
```

Description

3D camera property; indicates whether the camera of the 3D text cast member is automatically positioned to show all of the text (TRUE) or not (FALSE). This is useful when changing the text, font, fontsize, and other properties of the cast member.

This property is not valid with other types of 3D cast members.
Example

This statement sets the `autoCameraPosition` property of the cast member named Headline to `FALSE`. When the cast member is displayed in 3D mode, the camera will not be positioned automatically.

```
member("Headline").autoCameraPosition = FALSE
```

See also

`displayMode`

autoMask

Usage

```
member(whichCursorCastMember).autoMask
the autoMask of member whichCastMember
```

Description

Cast member property; specifies whether the white pixels in the animated color cursor cast member `whichCursorCastMember` are transparent, allowing the background to show through (`TRUE`, default), or opaque (`FALSE`).

Example

In this script, when the custom animated cursor stored in cast member 5 enters the sprite, the automask is turned on so that the background of the sprite will show through the white pixels. When the cursor leaves the sprite, the automask is turned off.

```
-- Lingo syntax
on mouseEnter
  member 5.autoMask = TRUE
end

on mouseLeave
  member 5.autoMask = FALSE
end
```

Using traditional Lingo syntax, the script is written as:

```
on mouseEnter
  set the autoMask of member 5 = TRUE
end

on mouseLeave
  set the autoMask of member 5 = FALSE
end
```
autoTab

Usage

-- Lingo syntax
memberObjRef.autoTab

// JavaScript syntax
memberObjRef.autoTab;

Description

Cast member property; determines the effect that pressing the Tab key has on the editable field or text cast member specified by whichCastMember. The property can be made active (TRUE) or inactive (FALSE). Tabbing order depends on sprite number order, not position on the Stage.

Example

This statement causes the cast member Comments to automatically advance the insertion point to the next editable field or text sprite after the user presses Tab.

-- Lingo syntax
member ("Comments").autotab = TRUE

// JavaScript syntax
member ("Comments").autotab = true;

axisAngle

Usage

member(whichCastmember).model(whichModel).transform.axisAngle
member(whichCastmember).camera(whichCamera).transform.axisAngle
member(whichCastmember).light(whichLight).transform.axisAngle
member(whichCastmember).group(whichGroup).transform.axisAngle
transformReference.axisAngle

Description

3D transform property; describes the transform's rotation as an axis/angle pair.

The axisAngle property is a linear list containing a vector (the axis) and a float (the angle). The vector is the axis around which the transform is rotated. The float is the amount, in degrees, of rotation.

The default value of this property is [vector(1.0000, 0.0000, 0.0000), 0.0000].

Example

This statement shows the rotation of the model named Mailbox as an axisAngle. The model is rotated 145.5 degrees counterclockwise about the y axis.

put member("Yard").model("Mailbox").transform.axisAngle
-- [vector(0.0000, 1.0000, 0.0000), -145.5000]

See also

rotation (transform)
back

Usage
member(whichCastmember).modelResource(whichModelResource).back

Description
3D #box model resource property; indicates whether the side of the box intersected by its +Z axis is sealed (TRUE) or open (FALSE).

The default value for this property is TRUE.

Example
This statement sets the back property of the model resource named Crate to FALSE, meaning the back of this box will be open.
member("3D World").modelResource("Crate").back = FALSE

See also
bottom (3D), front (3D), top (3D), left (3D), right (3D)

backColor

Usage
-- Lingo syntax
spriteObjRef.backColor

// JavaScript syntax
spriteObjRef.backColor;

Description
Sprite property; sets the background color of a specified sprite according to the color value assigned. Read/write.

Setting backColor of a sprite is the same as choosing the background color from the Tool palette when the sprite is selected on the Stage. For the value that a script sets to last beyond the current sprite, the sprite must be a scripted sprite. The background color applies to all bitmap cast members, in addition to field, button, check box, and radio cast members.

The backColor value ranges from 0 to 255 for 8-bit color and from 0 to 15 for 4-bit color. The numbers correspond to the index number of the background color in the current palette. (A color’s index number appears in the color palette’s lower left corner when you click the color.)

If this property is set on bitmap cast members that are deeper than 1-bit, the backColor may not be seen if the background of the bitmap is not visible.

If the blend of a sprite is less than 100 but greater than 0, the backColor will mix with the transparent colors.

Note: It is recommended that the newer bgColor property be used instead of the backColor property.
Example

The following statement sets the variable `oldColor` to the background color of sprite 5:

```
-- Lingo syntax
oldColor = sprite(5).backColor

// JavaScript syntax
var oldColor = sprite(5).backColor;
```

The following statement randomly changes the background color of a random sprite between sprites 11 and 13 to color number 36:

```
-- Lingo syntax
sprite(10 + random(3)).backColor = 36

// JavaScript syntax
sprite(10 + random(3)).backColor = 36;
```

See also

`Sprite`

**backdrop**

Usage

```
sprite(whichSprite).camera{index}.backdrop[index].loc
member(whichCastmember).camera(whichCamera).backdrop[index].loc
sprite(whichSprite).camera{index}.backdrop[index].source
member(whichCastmember).camera(whichCamera).backdrop[index].source
sprite(whichSprite).camera{index}.backdrop[index].scale
member(whichCastmember).camera(whichCamera).backdrop[index].scale
sprite(whichSprite).camera{index}.backdrop[index].rotation
member(whichCastmember).camera(whichCamera).\b
toptext
sprite(whichSprite).camera{index}.backdrop[index].regPoint
member(whichCastmember).camera(whichCamera).\b
sprite(whichSprite).camera{index}.backdrop[index].blend
member(whichCastmember).camera(whichCamera).backdrop[index].blend
sprite(whichSprite).camera{index}.backdrop.count
member(whichCastmember).camera(whichCamera).backdrop.count
```

Description

3D camera property; a 2D image that is rendered on the camera's projection plane. All models in the camera's view appear in front of the backdrop.

Backdrops have the following properties:

*Note:* These properties can also be used to get, set, and manipulate overlays. For detailed information, see the individual property entries.

**loc** *(backdrop and overlay)* indicates the 2D location of the backdrop, as measured from the upper left corner of the sprite.

**source** indicates the texture used by the backdrop.

**scale** *(backdrop and overlay)* is the number by which the height and width of the texture are multiplied to determine the dimensions of the backdrop.
rotation (backdrop and overlay) is the amount by which the backdrop is rotated about its regPoint.

regPoint (3D) indicates the registration point of the backdrop.

blend (3D) indicates the opacity of the backdrop.

count (3D) indicates the number of items in the camera’s list of backdrops.

Use the following commands to create and remove backdrops:

addBackdrop creates a backdrop from a texture and adds it to the end of the camera’s list of backdrops.

insertBackdrop creates a backdrop from a texture and adds it to the camera’s list of backdrops at a specific index position.

removeBackdrop deletes the backdrop.

See also

overlay

backgroundColor

Usage

-- Lingo syntax
memberObjRef.backgroundColor

// JavaScript syntax
memberObjRef.backgroundColor;

Description

Vector shape cast member property; sets the background color of the specified cast member or sprite to the RGB color value assigned.

This property can be both tested and set.

Example

-- Lingo syntax
member("Archie").backgroundColor= color(255,255,255)

// JavaScript syntax
member("Archie").backgroundColor= color(255,255,255);

See also

bgColor (Window)

beepOn

Usage

-- Lingo syntax
_movie.beepOn

// JavaScript syntax
_movie.beepOn;
**Description**

Movie property; determines whether the computer automatically beeps when the user clicks on anything except an active sprite (TRUE), or not (FALSE, default). Read/write.

Scripts that set beepOn should be placed in frame or movie scripts.

**Example**

This statement sets beepOn to TRUE:

```
-- Lingo syntax
_movie.beepOn = TRUE

// JavaScript syntax
_movie.beepOn = true;
```

This statement sets beepOn to the opposite of its current setting:

```
-- Lingo syntax
_movie.beepOn = not(_movie.beepOn)

// JavaScript syntax
_movie.beepOn = !(_movie.beepOn);
```

**See also**

Movie

**bevelDepth**

**Usage**

```
member(whichTextCastmember).bevelDepth
member(which3DCastmember).modelResource(whichModelResource).\bevelDepth
```

**Description**

3D text property; indicates the degree of beveling on the 3D text.

For text cast members, this property has no effect unless the member’s displayMode property is set to #mode3D and its bevelType property is set to #miter or #round.

For extruded text in a 3D cast member, this property has no effect unless the model resource’s bevelType property is set to #miter or #round.

The range of this property is 0.0 to 10.0, and the default setting is 10.0.

**Example**

In this example, the cast member named Logo is a text cast member. This statement sets the bevelDepth of logo to 5.5. When logo is displayed in 3D mode, if its bevelType property is set to #miter or #round, the edges of its letters will exhibit dramatic beveling.

```
member("Logo").bevelDepth = 5.5
```

In this example, the model resource of the model named Slogan is extruded text. This statement sets the bevelDepth of Slogan’s model resource to 5. If the bevelType property of Slogan is set to #miter or #round, the edges of its letters will exhibit dramatic beveling.

```
member("scene").model("Slogan").resource.bevelDepth = 5
```
See also

bevelType, extrude3D, displayMode

bevelType

Usage

member(whichTextCastmember).bevelType
member(which3DCastmember).modelResource(whichModelResource).
bevelType

Description

3D text property; indicates the style of beveling applied to the 3D text.

For text cast members, this is a member property. For extruded text in a 3D cast member, this is a model resource property.

The bevelType property has the following possible values:

• #none
• #miter (the default)
• #round

Example

In this example, the cast member named Logo is a text cast member. This statement sets the bevelType of Logo to #round.

member("logo").beveltype = #round

In this example, the model resource of the model named Slogan is extruded text. This statement sets the bevelType of Slogan's model resource to #miter.

member("scene").model("Slogan").resource.bevelType = #miter

See also

bevelDepth, extrude3D, displayMode

bgColor (Window)

Usage

-- Lingo syntax
windowObjRef.bgColor

// JavaScript syntax
windowObjRef.bgColor;

Description

Window property; determines the background color of a window. Read/write.

Setting the bgColor property is equivalent to setting the color in the Movie Properties dialog box.

Example

This example sets the color of the window named Animals to an RGB value.

-- Lingo syntax
window("Animals").bgColor = color(255, 153, 0)
// JavaScript syntax
window("Animals").bgColor = color(255, 153, 0);

See also

Window

bgColor (Sprite, 3D Member)

Usage

sprite(whichSpriteNumber).bgColor
the bgColor of sprite whichSpriteNumber
the bgColor of the stage
(the stage).bgColor
member(which3dMember).bgcolor

Description

Sprite property, system property, and 3D cast member property; determines the background color of the sprite specified by whichSprite, the color of the Stage, or the background color of the 3D cast member. Setting the bgColor sprite property is equivalent to choosing the background color from the Tools window when the sprite is selected on the Stage. Setting the bgColor property for the Stage is equivalent to setting the color in the Movie Properties dialog box.

The sprite property has the equivalent functionality of the backColor sprite property, but the color value returned is a color object of whatever type has been set for that sprite.

This property can be tested and set.

Example

This example sets the color of the Stage to an RGB value.

Dot syntax:
(the stage).bgColor = rgb(255, 153, 0)

Verbose Lingo syntax:
set the bgColor of the stage = rgb(255, 153, 0)

See also

color(), backColor, backgroundColor

bias

Usage

member(whichCastmember).model(whichModel).lod.bias

Description

3D lod modifier property; indicates how aggressively the modifier removes detail from the model when its auto property is set to TRUE. This property has no effect when the modifier’s auto property is set to FALSE.

The range for this property is from 0.0 (removes all polygons) to +100.0 (removes no polygons). The default setting is 100.0.
The #lod modifier can only be added to models created outside of Director in 3D modeling programs. The value of the type property of the model resources used by these models is #fromFile. The modifier cannot be added to primitives created within Director.

Example
This statement sets the bias property of the lod modifier of the model named Spaceship to 10. If the lod modifier's auto property is set to TRUE, the modifier will very aggressively lower the level of detail of Spaceship as it moves away from the camera.

```
member("3D World").model("Spaceship").lod.bias = 10
```

See also

`lod (modifier), auto, level`

**bitmapSizes**

**Usage**

```
-- Lingo syntax
memberObjRef.bitmapSizes

// JavaScript syntax
memberObjRef.bitmapSizes;
```

**Description**
Font cast member property; returns a list of the bitmap point sizes that were included when the font cast member was created.

**Example**
This statement displays the bitmap point sizes that were included when cast member 11 was created:

```
-- Lingo syntax
put(member(11).bitmapSizes)

// JavaScript syntax
put(member(11).bitmapSizes);
```

See also

`recordFont, characterSet, originalFont`

**bitRate**

**Usage**

```
-- Lingo syntax
memberObjRef.bitRate

// JavaScript syntax
memberObjRef.bitRate;
```

**Description**
Shockwave Audio (SWA) cast member property; returns the bit rate, in kilobits per second (Kbps), of the specified SWA cast member that has been preloaded from the server.

The bitRate member property returns 0 until streaming begins.
Example

This behavior outputs the bit rate of an SWA cast member when the sprite is first encountered.

-- Lingo syntax
property spriteNum

on beginSprite (me)
  memName = sprite(spriteNum).member.name
  put("The bitRate of member"&&memName&&"is"&&member(memName).bitRate)
end

// JavaScript syntax
function beginSprite() {
  var memName = sprite(spriteNum).member.name;
  put("The bitRate of member " + memName + " is " + member(memName).bitRate);
}

bitsPerSample

Usage

-- Lingo syntax
memberObjRef.bitsPerSample

// JavaScript syntax
memberObjRef.bitsPerSample;

Description

Shockwave Audio (SWA) cast member property; indicates the bit depth of the original file that has been encoded for Shockwave Audio (SWA). This property is available only after the SWA sound begins playing or after the file has been preloaded using the preLoadBuffer command. This property can be tested but not set.

Example

This statement assigns the original bit rate of the file used in SWA streaming cast member Paul Robeson to the field cast member How Deep.

-- Lingo syntax
member("How Deep").text = member("Paul Robeson").bitsPerSample

// JavaScript syntax
member("How Deep").text = member("Paul Robeson").bitsPerSample;

blend (3D)

Usage

sprite(whichSprite).camera{index}.backdrop[index].blend
member(whichCastmember).camera(whichCamera).backdrop[index].blend
sprite(whichSprite).camera{index}.overlay[index].blend
member(whichCastmember).camera(whichCamera).overlay[index].blend
member(whichCastmember).model(whichModel).shader.blend
member(whichCastmember).model(whichModel).shaderList[[index]].blend
Description

3D backdrop, overlay, and #standard shader property; indicates the opacity of the backdrop, overlay, or shader.

Setting the blend property of a shader will have no effect unless the shader's transparent property is set to TRUE.

The range of this property is 0 to 100, and the default value is 100.

Example

This statement sets the blend property of the shader for the model named Window to 80. If the transparent property of Window's shader is set to TRUE, the model will be slightly transparent.

member("House").model("Window").shader.blend = 80

See also

bevelDepth, overlay, shadowPercentage, transparent

blend (Sprite)

Usage

-- Lingo syntax
spriteObjRef.blend

// JavaScript syntax
spriteObjRef.blend;

Description

Sprite property; returns or sets a sprite's blend value, from 0 to 100, corresponding to the blend values in the Sprite Properties dialog box. Read/write.

The possible colors depend on the colors available in the palette, regardless of the monitor's color depth.

For best results, use the blend ink with images that have a color depth greater than 8-bit.

Example

The following statement sets the blend value of sprite 3 to 40 percent.

-- Lingo syntax
sprite(3).blend = 40

// JavaScript syntax
sprite(3).blend = 40;

This statement displays the blend value of sprite 3 in the Message window:

-- Lingo syntax
put(sprite(3).blend)

// JavaScript syntax
put(sprite(3).blend);

See also

blendLevel, Sprite
blendConstant

**Usage**

```plaintext
member(whichCastmember).shader(whichShader).blendConstant
member(whichCastmember).model(whichModel).shader.blendConstant
member(whichCastmember).model(whichModel).shaderList[[index]].
  blendConstant
```

**Description**

3D #standard shader property; indicates the blending ratio used for the first texture layer of the shader.

If the shader's useDiffuseWithTexture property is set to TRUE, the texture blends with the color set by the shader's diffuse property. If useDiffuseWithTexture is FALSE, white is used for blending.

Each of the other texture layers blends with the texture layer below it. Use the blendConstantList property to control blending in those texture layers.

The blendConstant property works only when the shader's blendSource property is set to #constant. For more information, see blendSource and blendSourceList.

The range of this property is 0 to 100; the default is 50.

**Example**

In this example, the shader list of the model named MysteryBox contains six shaders. This statement sets the blendConstant property of the second shader to 20. This property is affected by the settings of the blendFunction, blendFunctionList, blendSource, and blendSourceList properties.

```plaintext
member("Level2").model("MysteryBox").shaderList[2].
  blendConstant = 20
```

See also:

blendConstantList, blendFunction, blendFunctionList, blendSource, blendSourceList, useDiffuseWithTexture, diffuse, diffuseColor

blendConstantList

**Usage**

```plaintext
member(whichCastmember).shader(whichShader).blendConstantList
member(whichCastmember).model(whichModel).shader.blendConstantList[[index]]
member(whichCastmember).model(whichModel).shaderList[[index]].
  blendConstantList[[index]]
```

**Description**

3D #standard shader property; indicates the ratio used for blending a texture layer of the shader with the texture layer below it.

The shader's texture list and the blend constant list both have eight index positions. Each index position in the blend constant list controls blending for the texture at the corresponding index position in the texture list. You can set all index positions of the list to the same value at one time by not specifying the optional index parameter. Use the index parameter to set the list one index position at a time.
The `blendConstantList` property works only when the `blendSource` property of the corresponding texture layer is set to `#constant`.

The range of this property is 0 to 100; the default is 50.

**Example**

In this example, the shader list of the model named `MysteryBox` contains six shaders. This statement shows the `blendConstant` property of each of the textures used by the second shader. This property is affected by the settings of the `blendFunction, blendFunctionList, blendSource, and blendSourceList` properties.

```plaintext
put member("Level2").model("MysteryBox").shaderList[2].\
   blendConstantList
   -- [20.0000, 50.0000, 50.0000, 50.0000, 20.0000, 50.0000, \
      50.0000, 50.0000]
```

See also

`blendConstant, blendFunction, blendFunctionList, blendSource, blendSourceList, useDiffuseWithTexture, diffuse, diffuseColor`

**blendFactor**

**Usage**

```plaintext
member(whichCastmember).model(whichModel).keyframePlayer.\
   blendFactor
member(whichCastmember).model(whichModel).bonesPlayer.blendFactor
```

**Description**

3D `keyframePlayer` and `bonesPlayer` modifier property; indicates the amount by which a motion is combined with the motion that preceded it.

The range of this property is 0 to 100, and the default value is 0.

`blendFactor` is used only when the `autoblend` property of the modifier is set to `FALSE`. If the value of the `blendFactor` property is 100, the current motion will have none of the characteristics of the motion that preceded it. If the value of `blendFactor` is 0, the current motion will have all of the characteristics of the motion that preceded it and none of its own. If the value of `blendFactor` is 50, the current motion will be a synthesis equally composed of its own characteristics and those of the motion that preceded it. The value `blendFactor` can be varied over time to create transitions unlike the linear transition created when the modifier's `autoblend` property is set to `TRUE`.

**Example**

This statement sets the `blendFactor` property of model `Alien3` to 50. If the modifier's `autoblend` property is `FALSE`, each motion in the playlist of the `keyframePlayer` for `Alien3` will be an even mixture of itself and the motion that preceded it.

```plaintext
member("newaliens").model("Alien3").keyframePlayer.blendFactor = 50
```

See also

`autoblend, keyframePlayer (modifier)`
blendFunction

Usage

member(whichCastmember).shader(whichShader).blendFunction
member(whichCastmember).model(whichModel).shader.blendFunction
member(whichCastmember).model(whichModel).shaderList[[index]].
  blendFunction

Description

3D #standard shader property; indicates the type of blending used by the first texture layer of the shader.

If the shader’s useDiffuseWithTexture property is set to TRUE, the texture blends with the color set by the shader’s diffuse property. If useDiffuseWithTexture is FALSE, white is used for blending.

Each of the other texture layers blends with the texture layer below it. Use the blendFunctionList property to control blending in those texture layers.

The blendFunction property can have the following values:

- #multiply multiplies the RGB values of the texture layer by the color being used for blending (see above).
- #add adds the RGB values of the texture layer to the color being used for blending, and then clamps to 255.
- #replace prevents the texture from being blended with the color set by the shader’s diffuse property.
- #blend combines the colors of the texture layer with the color being used for blending in the ratio set by the blendConstant property.

The default value of this property is #multiply.

Example

In this example, the shader list of the model named MysteryBox contains six shaders. This statement sets the blendFunction property of the second shader to #blend. This enables the settings of the blendSource, blendSourceList, blendConstant, and blendConstantList properties.

member("Level2").model("MysteryBox").shaderList[2].
  blendFunction = #blend

See also

blendConstant, blendConstantList, blendFunctionList, blendSource, blendSourceList, useDiffuseWithTexture, diffuse, diffuseColor
blendFunctionList

Usage

member(whichCastmember).shader(whichShader).\blendFunctionList[[index]]
member(whichCastmember).model(whichModel).shader.\blendFunctionList[[index]]
member(whichCastmember).model(whichModel).shaderList[[index]].\blendFunctionList[[index]]

Description

3D #standard shader property; a linear list that indicates the manner in which each texture layer blends with the texture layer below it.

The shader's texture list and blend function list both have eight index positions. Each index position in the blend function list controls blending for the texture at the corresponding index position in the texture list. You can set all index positions of the list to the same value at one time by not specifying the optional index parameter. Use the index parameter to set the list one index position at a time.

Each index position of the blend function list can have one of the following values:

- #multiply multiplies the RGB values of the texture layer by the RGB values of the texture layer below it.
- #add adds the RGB values of the texture layer to the RGB values of the texture layer below it, and then clamps to 255.
- #replace causes the texture to cover the texture layer below it. No blending occurs.
- #blend causes blending to be controlled by the value of the blendSource property, which allows alpha blending.

The default value of this property is #multiply.

Example

In this example, the shaderList property of the model named MysteryBox contains six shaders. This statement shows that the value of the fourth index position of the blendFunctionList property of the second shader is set to #blend. Blending of the fourth texture layer of the second shader of the model will be controlled by the settings of the blendSource, blendSourceList, blendConstant, blendConstantList, diffuse, diffuseColor, and useDiffuseWithTexture properties.

put member("Level2").model("MysteryBox").shaderList[2].\blendFunctionList[4]
-- #blend

See also

blendConstant, blendConstantList, blendFunction, blendSource, blendSourceList, diffuse, diffuseColor, useDiffuseWithTexture
blendLevel

Usage

sprite(whichSpriteNumber).blendLevel
the blendLevel of sprite whichSpriteNumber

Description

Sprite property; allows the current blending value of a sprite to be set or accessed. The possible range of values is from 0 to 255. This differs from the Sprite Inspector, which shows values in the range 0 to 100. The results are the same, the scales simply differ.

This property is the equivalent of the blend sprite property.

Example

sprite(3).blendlevel = 99

See also

blend (Sprite)

blendRange

Usage

member(whichCastmember).modelResource(whichModelResource)\blendRange.start
modelResourceObjectReference.blendRange.end
member(whichCastmember).modelResource(whichModelResource)\blendRange.start
modelResourceObjectReference.blendRange.end

Description

3D property; when used with a model resource whose type is #particle, allows you to get or set the start and end of the model resource's blend range.

The opacity of particles in the system is interpolated linearly between blendRange.start and blendRange.end over the lifetime of each particle.

This property's value must be greater than or equal to 0.0 and less than or equal to 100.0. The default value for this property is 100.0.

Example

This statement sets the blendRange properties of model resource ThermoSystem, which is of the type #particle.

The first line sets the start value to 100, and the second line sets the end value to 0. The effect of this statement is that the particles of ThermoSystem are fully opaque when they first appear, and then gradually fade to transparent during their lifetime.

member("Heater").modelResource("ThermoSystem").blendRange.\start = 100.0
member("Heater").modelResource("ThermoSystem").blendRange.\end = 0.0
**blendSource**

**Usage**

```plaintext
member(whichCastmember).shader(whichShader).blendSource
member(whichCastmember).model(whichModel).shader.blendSource
member(whichCastmember).model(whichModel).shaderList[[index]].\
  blendSource
```

**Description**

3D `#standard` shader property; indicates whether blending of the first texture layer in the shader's texture list is based on the texture's alpha information or a constant ratio.

If the shader's `useDiffuseWithTexture` property is set to `TRUE`, the texture blends with the color set by the shader's `diffuse` property. If `useDiffuseWithTexture` is `FALSE`, white is used for blending.

Each of the other texture layers blends with the texture layer below it. Use the `blendSourceList` property to control blending in those texture layers.

The `blendSource` property works only when the shader's `blendFunction` property is set to `#blend`.

The possible values of this property are as follows:

- `#alpha` causes the alpha information in the texture to determine the blend ratio of each pixel of the texture with the color being used for blending (see above).
- `#constant` causes the value of the shader's `blendConstant` property to be used as the blend ratio for all the pixels of the texture.

The default value of this property is `#constant`.

**Example**

In this example, the shader list of the model named MysteryBox contains six shaders. This statement sets the `blendSource` property of the first texture used by the second shader to `#constant`. This enables the settings of the `blendConstant` and `blendConstantList` properties.

```plaintext
member("Level2").model("MysteryBox").shaderList[2].\
  blendSource = #constant
```

**See also**

`blendSourceList`, `blendFunction`, `blendFunctionList`, `blendConstant`, `blendConstantList`, `useDiffuseWithTexture`, `diffuse`, `diffuseColor`

**blendSourceList**

**Usage**

```plaintext
member(whichCastmember).shader(whichShader).\
  blendSourceList[[index]]
member(whichCastmember).model(whichModel).shader.\
  blendSourceList[[index]]
member(whichCastmember).model(whichModel).\n  shaderList[[index]].blendSourceList[[index]]
```
Description

3D #standard shader property; indicates whether blending of a texture layer with the texture layers below it is based on the texture's alpha information or a constant ratio.

The shader's texture list and the blend source list both have eight index positions. Each index position in the blend source list controls blending for the texture at the corresponding index position in the texture list. You can set all index positions of the list to the same value at one time by not specifying the optional index parameter. Use the index parameter to set the list one index position at a time.

The `blendSourceList` property only works when the `blendFunction` property of the corresponding texture layer is set to `#blend`. See `blendFunction` and `blendFunctionList` for more information.

The possible values of this property are as follows:

- `#alpha` causes the alpha information in the texture to determine the blend ratio of each pixel of the texture layer with the layer below it.
- `#constant` causes the value of the `blendConstant` property of the corresponding texture layer to be used as the blend ratio for all of the pixels of the texture layer. See `blendConstant` and `blendConstantList` for more information.

The default value of this property is `#constant`.

Example

In this example, the shader list of the model MysteryBox contains six shaders. Each shader has a texture list that contains up to eight textures. This statement shows that the `blendSource` property of the fourth texture used by the second shader is set to `#constant`. This enables the settings of the `blendConstant, blendConstantList, and useDiffuseWithTexture` properties.

```plaintext
member("Level2").model("MysteryBox").shaderList[2].
  blendSourceList[4] = #constant
```

- `blendSource, blendFunction, blendFunctionList, blendConstant, blendConstantList, useDiffuseWithTexture, diffuse, diffuseColor`

blendTime

Usage

```plaintext
member(whichCastmember).model(whichModel).keyframePlayer.
  blendTime
member(whichCastmember).model(whichModel).bonesPlayer.blendTime
```

Description

3D `keyframePlayer` and `bonesPlayer` modifier property; determines the duration, in milliseconds, of the transition between motions in the playlist of the modifier for the model.

The `blendTime` property works in conjunction with the modifier's `autoBlend` property. When `autoBlend` is set to `TRUE`, the modifier creates a linear transition to the model's currently playing motion from the motion that preceded it. The value of the `blendTime` property is the length of that transition. The `blendTime` property is ignored if `autoBlend` is set to `FALSE`.

The default setting of this property is 500.
Example

This statement sets the length of the transition between motions in the playlist of the modifier for the model named Alien5 to 1200 milliseconds.

```
member("newaliens").model("Alien5").keyframePlayer.
  blendTime = 1200
```

See also

autoblend, blendFactor

bone

Usage

```
member(whichCastmember).modelResource(whichModelResource).\n  bone.count
member(whichCastmember).model(whichModel).bonesPlayer.\n  bone[index].transform
member(whichCastmember).model(whichModel).bonesPlayer.\n  bone[index].worldTransform
```

Description

3D element; a bone is structural element of a model resource authored in a 3D modeling program. Bones cannot be created, deleted, or rearranged in Director.

Bones (#bones) motions, which also must be scripted in a 3D modeling program, act upon the bone structure of a model resource, and are managed in Director by the bonesPlayer modifier.

See also

count (3D), bonesPlayer (modifier), transform (property), worldTransforn

bonesPlayer (modifier)

Usage

```
member(whichCastmember).model(whichModel).
  bonesPlayer.whichBonesPlayerProperty
```

Description

3D modifier; manages the use of motions by models. The motions managed by the bonesPlayer modifier animate segments, called bones, of the model.

Motions and the models that use them must be created in a 3D modeling program, exported as W3D files, and then imported into a movie. Motions cannot be applied to model primitives created within Director.

Adding the bonesPlayer modifier to a model by using the addModifier command allows access to the following bonesPlayer modifier properties:

- **playing (3D)** indicates whether a model is executing a motion.
- **playlist** is a linear list of property lists containing the playback parameters of the motions that are queued for a model.
- **currentTime (3D)** indicates the local time, in milliseconds, of the currently playing or paused motion.
**playRate (3D)** is a number that is multiplied by the `scale` parameter of the `play()` or `queue()` command to determine the playback speed of the motion.

**playlist.count (3D)** returns the number of motions currently queued in the playlist.

**rootLock** indicates whether the translational component of the motion is used or ignored.

**currentLoopState** indicates whether the motion plays once or repeats continuously.

**blendTime** indicates the length of the transition created by the modifier between motions when the modifier's `autoBlend` property is set to `TRUE`.

**autoblend** indicates whether the modifier creates a linear transition to the currently playing motion from the motion that preceded it.

**blendFactor** indicates the degree of blending between motions when the modifier's `autoBlend` property is set to `FALSE`.

**bone[boneId].transform** indicates the transform of the bone relative to the parent bone. You can find the `boneId` value by testing the `getBoneID` property of the model resource. When you set the transform of a bone, it is no longer controlled by the current motion, and cannot be returned to the control of the motion. Manual control ends when the current motion ends.

**bone[boneId].getWorldTransform** returns the world-relative transform of the bone.

**lockTranslation** indicates whether the model can be displaced from the specified planes.

**positionReset** indicates whether the model returns to its starting position after the end of a motion or each iteration of a loop.

**rotationReset** indicates the rotational element of a transition from one motion to the next, or the looping of a single motion.

**Note:** For more detailed information about these properties, see the individual property entries.

The **bonesPlayer** modifier uses the following commands:

**pause() (3D)** halts the motion currently being executed by the model.

**play() (3D)** initiates or unpauses the execution of a motion.

**playNext() (3D)** initiates playback of the next motion in the playlist.

**queue() (3D)** adds a motion to the end of the playlist.

The **bonesPlayer** modifier generates the following events, which are used by handlers declared in the `registerForEvent()` and `registerScript()` commands. The call to the declared handler includes three arguments: the event type (either `#animationStarted` or `#animationEnded`), the name of the motion, and the current time of the motion. For detailed information about notification events, see `registerForEvent()`.

`#animationStarted` is sent when a motion begins playing. If blending is used between motions, the event is sent when the transition begins.

`#animationEnded` is sent when a motion ends. If blending is used between motions, the event is sent when the transition ends.

**See also**

`keyframePlayer (modifier), addModifier, modifiers, modifier`
border

Usage
--- Lingo syntax
memberObjRef.border

// JavaScript syntax
memberObjRef.border;

Description
Field cast member property; indicates the width, in pixels, of the border around the specified field cast member.

Example
This statement makes the border around the field cast member Title 10 pixels wide.
---Lingo syntax
member("Title").border = 10

// JavaScript syntax
member("Title").border = 10;

bottom

Usage
--- Lingo syntax
spriteObjRef.bottom

// JavaScript syntax
spriteObjRef.bottom;

Description
Sprite property; specifies the bottom vertical coordinate of the bounding rectangle of a sprite. Read/write.

Example
This statement assigns the vertical coordinate of the bottom of the sprite numbered (i + 1) to the variable named lowest.
--- Lingo syntax
lowest = sprite(i + 1).bottom

// JavaScript syntax
var lowest = sprite(i + 1).bottom;

See also
Sprite
bottom (3D)

**Usage**

```
member(whichCastmember).modelResource(whichModelResource).bottom
```

**Description**

3D #box model resource property; indicates whether the side of the box intersected by its -Y axis is sealed (TRUE) or open (FALSE).

The default value for this property is TRUE.

**Example**

This statement sets the bottom property of the model resource named GiftBox to TRUE, meaning the bottom of this box will be closed.

```
member("3D World").modelResource("GiftBox").bottom = TRUE
```

**See also**

back, front, top (3D), left (3D), right (3D), bottomCap

bottomCap

**Usage**

```
member(whichCastmember).modelResource(whichModelResource).bottomCap
```

**Description**

3D #cylinder model resource property; indicates whether the end of the cylinder intersected by its -Y axis is sealed (TRUE) or open (FALSE).

The default value for this property is TRUE.

**Example**

This statement sets the bottomCap property of the model resource named Tube to FALSE, meaning the bottom of this cylinder will be open.

```
member("3D World").modelResource("Tube").bottomCap = FALSE
```

**See also**

topCap, bottomRadius, bottom (3D)

bottomRadius

**Usage**

```
member(whichCastmember).modelResource(whichModelResource).bottomRadius
```

**Description**

3D #cylinder model resource property; indicates the radius, in world units, of the end of the cylinder that is intersected by its -Y axis.

The default value for this property is 25.
Example

This statement sets the `bottomRadius` property of the model resource named `Tube` to 38.5.

```
member("3D World").modelResource("Tube").bottomRadius = 38.5
```

See also

topRadius, bottomCap

**bottomSpacing**

Usage

```
-- Lingo syntax
chunkExpression.bottomSpacing

// JavaScript syntax
chunkExpression.bottomSpacing;
```

Description

Text cast member property; enables you to specify additional spacing applied to the bottom of each paragraph in the `chunkExpression` portion of the text cast member.

The value itself is an integer, where less than 0 indicates less spacing between paragraphs and greater than 0 indicates more spacing between paragraphs.

The default value is 0, which results in default spacing between paragraphs.

*Note:* This property, like all text cast member properties, supports only dot syntax.

Example

This example adds spacing after the first paragraph in cast member News Items.

```
-- Lingo syntax
member("News Items").paragraph[1].bottomSpacing=20

// JavaScript syntax
member("News Items").getPropRef("paragraph", 1).bottomSpacing=20;
```

See also
top (3D)

**boundary**

Usage

```
member(whichCastmember).model(whichModel).inker.boundary
member(whichCastmember).model(whichModel).toon.boundary
```

Description

3D inker and toon modifier property; allows you to set whether a line is drawn at the edges of a model.

The default setting for this property is `TRUE`. 
Example
This statement sets the boundary property of the inker modifier applied to the model named Box to TRUE. Lines will be drawn at the edges of the surface of the model.

member("shapes").model("Box").inker.boundary = TRUE

See also
lineColor, lineOffset, silhouettes, creases

boundingSphere
Usage
member(whichCastmember).model(whichModel).boundingSphere
member(whichCastmember).group(whichGroup).boundingSphere
member(whichCastmember).light(whichLight).boundingSphere
member(whichCastmember).camera(whichCamera).boundingSphere

Description
3D model, group, light, and camera property; describes a sphere that contains the model, group, light, or camera and its children.

The value of this property is a list containing the vector position of the center of the sphere and the floating-point length of the sphere's radius.

This property can be tested but not set.

Example
This example displays the bounding sphere of a light in the message window.

put member("newAlien").light[5].boundingSphere
-- [vector(166.8667, -549.6362, 699.5773), 1111.0039]

See also
debug

boxDropShadow
Usage
-- Lingo syntax
memberObjRef.boxDropShadow

// JavaScript syntax
memberObjRef.boxDropShadow;

Description
Cast member property; determines the size, in pixels, of the drop shadow for the box of the field cast member specified by whichCastMember.
Example

This statement makes the drop shadow of field cast member Title 10 pixels wide.

--Lingo syntax
member("Title").boxDropShadow = 10

// JavaScript syntax
member("Title").boxDropShadow = 10;

boxType

Usage

-- Lingo syntax
memberObjRef.boxType

// JavaScript syntax
memberObjRef.boxType;

Description

Cast member property; determines the type of text box used for the specified cast member. The possible values are #adjust, #scroll, #fixed, and #limit.

Example

This statement makes the box for field cast member Editorial a scrolling field.

--Lingo syntax
member("Editorial").boxType = #scroll

// JavaScript syntax
member("Editorial").boxType = symbol("scroll");

brightness

Usage

member(whichCastmember).shader(whichShader).brightness
member(whichCastmember).model(whichModel).shader.brightness
member(whichCastmember).model(whichModel).shaderList[[index]].brightness

Description

3D #newsprint and #engraver shader property; indicates the amount of white blended into the shader.

The range of this property is 1 to 100; the default value is 0.

Example

This statement sets the brightness of the shader used by the model named gbCyl2 to half of its maximum value.

member("scene").model("gbCyl2").shader.brightness = 50

See also

ewShader
**broadcastProps**

**Usage**

-- Lingo syntax
```lingo
memberObjRef.broadcastProps
```

// JavaScript syntax
```javascript
memberObjRef.broadcastProps;
```

**Description**

Cast member property; controls whether changes made to a Flash or Vector shape cast member are immediately broadcast to all of its sprites currently on the Stage (TRUE) or not (FALSE).

When this property is set to FALSE, changes made to the cast member are used only as defaults for new sprites and don't affect sprites on the Stage.

The default value for this property is TRUE, and it can be both tested and set.

**Example**

This frame script assumes that a Flash movie cast member named Navigation Movie has been set up with its broadcastProps property set to FALSE. The script momentarily allows changes to a Flash movie cast member to be broadcast to its sprites currently on the Stage. It then sets the viewScale property of the Flash movie cast member, and that change is broadcast to its sprite. The script then prevents the Flash movie from broadcasting changes to its sprites.

-- Lingo syntax
```lingo
on enterFrame
    member("Navigation Movie").broadcastProps = TRUE
    member("Navigation Movie").viewScale = 200
    member("Navigation Movie").broadcastProps = FALSE
end
```

// JavaScript syntax
```javascript
function enterFrame() {
    member("Navigation Movie").broadcastProps = 1;
    member("Navigation Movie").viewScale = 200;
    member("Navigation Movie").broadcastProps = 0;
}
```

**bufferSize**

**Usage**

-- Lingo syntax
```lingo
memberObjRef.bufferSize
```

// JavaScript syntax
```javascript
memberObjRef.bufferSize;
```

**Description**

Flash cast member property; controls how many bytes of a linked Flash movie are streamed into memory at one time. The bufferSize member property can have only integer values. This property has an effect only when the cast member's preload property is set to FALSE.

This property can be tested and set. The default value is 32,768 bytes.
Example

This `startMovie` handler sets up a Flash movie cast member for streaming and then sets its `bufferSize` property.

-- Lingo syntax
on startMovie
  member.("Flash Demo").preload = FALSE
  member.("Flash Demo").bufferSize = 65536
end

// JavaScript syntax
function startMovie() {
  member.("Flash Demo").preload = 0;
  member.("Flash Demo").bufferSize = 65536;
}

See also
  `bytesStreamed`, `preloadRAM`, `stream()`, `streamMode`

**buttonCount**

**Usage**

-- Lingo syntax
dvdObjRef.buttonCount

// JavaScript syntax
dvdObjRef.buttonCount;

**Description**

DVD property; returns the number of available buttons on the current DVD menu. Read-only.

**See also**
  `DVD`

**buttonsEnabled**

**Usage**

-- Lingo syntax
memberOrSpriteObjRef.buttonsEnabled

// JavaScript syntax
memberOrSpriteObjRef.buttonsEnabled;

**Description**

Flash cast member property and sprite property; controls whether the buttons in a Flash movie are active (`TRUE`, default) or inactive (`FALSE`). Button actions are triggered only when the `actionsEnabled` property is set to `TRUE`.

This property can be tested and set.
Example

This handler accepts a sprite reference and toggles the sprite’s `buttonsEnabled` property on or off.

```-- Lingo syntax
on ToggleButtons(whichSprite)
    sprite(whichSprite).buttonsEnabled = \not(sprite(whichSprite).buttonsEnabled)
end
// JavaScript syntax
function ToggleActions(whichSprite) {
    sprite(whichSprite).buttonsEnabled = !(sprite(whichSprite).buttonsEnabled);
}
```

See also

`actionsEnabled`

**buttonStyle**

Usage

```-- Lingo syntax
_movie.buttonStyle
// JavaScript syntax
_movie.buttonStyle;
```

Description

Movie property; determines the visual response of buttons while the mouse button is held down. Read/write.

This property applies only to buttons created with the Button tool in the Tool palette.

The `buttonStyle` property can have these values:

- 0 (list style: default)—Subsequent buttons are highlighted when the pointer passes over them. Releasing the mouse button activates the script associated with that button.
- 1 (dialog style)—Only the first button clicked is highlighted. Subsequent buttons are not highlighted. Releasing the mouse button while the pointer is over a button other than the original button clicked does not activate the script associated with that button.

Example

The following statement sets the `buttonStyle` property to 1:

```-- Lingo syntax
_movie.buttonStyle = 1
// JavaScript syntax
_movie.buttonStyle = 1;
```
This statement remembers the current setting of the buttonStyle property by putting the current buttonStyle value in the variable buttonStyleValue:

-- Lingo syntax
buttonStyleValue = _movie.buttonStyle

// JavaScript syntax
var buttonStyleValue = _movie.buttonStyle;

See also
Movie

**buttonType**

**Usage**

member(whichCastMember).buttonType
the buttonType of member whichCastMember

**Description**

Button cast member property; indicates the specified button cast member's type. Possible values are #pushButton, #checkBox, and #radioButton. This property applies only to buttons created with the button tool in the Tool palette.

**Example**

This statement makes the button cast member Editorial a check box.

Dot syntax:

member("Editorial").buttonType = #checkBox

Verbose syntax:

set the buttonType of member "Editorial" to #checkBox

**bytesStreamed**

**Usage**

-- Lingo syntax
memberObjRef.bytesStreamed

// JavaScript syntax
memberObjRef.bytesStreamed;

**Description**

Flash and Shockwave Audio cast member property; indicates the number of bytes of the specified cast member that have been loaded into memory. The bytesStreamed property returns a value only when the Director movie is playing. It returns an integer value.

This property can be tested but not set.

**Example**

This handler accepts a cast member reference as a parameter, and it then uses the stream command to load the cast member into memory. Every time it streams part of the cast member into memory, it uses the bytesStreamed property to report in the Message window how many bytes have been streamed.
-- Lingo syntax
on fetchMovie(whichFlashMovie)
    repeat while member(whichFlashMovie).percentStreamed < 100
        stream(member(whichFlashMovie))
        put("Number of bytes streamed:" && member(whichFlashMovie).bytesStreamed)
    end repeat
end

// JavaScript syntax
function fetchMovie(whichFlashMovie)
    var i = member(whichFlashMovie).percentStreamed;
    while(i < 100) {
        stream(member(whichFlashMovie));
        trace( "Number of bytes streamed: " +
            member(whichFlashMovie).bytesStreamed);
    }
}

See also
    bufferSize, percentStreamed (Member), stream()

bytesStreamed (3D)

Usage
    member(whichCastMember).bytesStreamed

Description
    3D cast member property; indicates how much of the initial file import or the last requested file load has loaded.

Example
    This statement shows that 325,300 bytes of the cast member named Scene have been loaded.
    put member("Scene").bytesStreamed
    -- 325300

See also
    streamSize (3D), state (3D)

camera

Usage
    member(whichCastMember).camera(whichCamera)
    member(whichCastMember).camera[index]
    member(whichCastMember).camera[whichCamera].whichCameraProperty
    sprite(whichSprite).camera[index].whichCameraProperty
    sprite(whichSprite).camera[index].whichCameraProperty

Description
    3D element; an object at a vector position from which the 3D world is viewed.

    Each sprite has a list of cameras. The view from each camera in the list is displayed on top of the view from camera with lower index positions. You can set the rect (camera) property of each camera to display multiple views within the sprite.
Cameras are stored in the camera palette of the cast member. Use the `newCamera` and `deleteCamera` commands to create and delete cameras in a 3D cast member.

The `camera` property of a sprite is the first camera in the list of cameras of the sprite. The camera referred to by `sprite(whichSprite).camera` is the same as `sprite(whichSprite).camera(1)`. Use the `addCamera` and `deleteCamera` commands to build the list of cameras in a 3D sprite.

For a complete list of camera properties and commands, see the Using Director topics in the Director Help Panel.

Example

This statement sets the camera of sprite 1 to the camera named TreeCam of the cast member named Picnic.

```lisp
sprite(1).camera = member("Picnic").camera("TreeCam")
```

This statement sets the camera of sprite 1 to camera 2 of the cast member named Picnic.

```lisp
sprite(1).camera = member("Picnic").camera[2]
```

`bevelDepth`, `overlay`, `modelUnderLoc`, `spriteSpaceToWorldSpace`, `fog`, `clearAtRender`

cameraPosition

Usage

```lisp
member(whichCastMember).cameraPosition
sprite(whichSprite).cameraPosition
```

Description

3D cast member and sprite property; indicates the position of the default camera.

The default value of this property is `vector(0, 0, 250)`. This is the position of the default camera in a newly created 3D cast member.

Example

This statement shows that the position of the default camera of the cast member named Babyland is the vector `-117.5992, -78.9491, 129.0254`.

```lisp
member("Babyland").cameraPosition = vector(-117.5992, -78.9491, 129.0254)
```

See also

`cameraRotation`, `autoCameraPosition`
**cameraRotation**

**Usage**

```plaintext
member(whichCastMember).cameraRotation
sprite(whichSprite).cameraRotation
```

**Description**

3D cast member and sprite property; indicates the position of the default camera.

The default value of this property is vector(0, 0, 0). This is the rotation of the default camera in a newly created 3D cast member.

**Example**

This statement shows that the rotation of the default camera of the cast member named Babyland is the vector (82.6010, -38.8530, -2.4029).

```plaintext
member("babyland").cameraRotation = vector(82.6010, -38.8530, -2.4029)
```

**See also**

cameraPosition, autoCameraPosition

**castLib**

**Usage**

```plaintext
-- Lingo syntax
_movie.castLib[castNameOrNum]

// JavaScript syntax
_movie.castLib[castNameOrNum];
```

**Description**

Movie property; provides named or indexed access to the cast libraries of a movie, whether the movie is active or not. Read-only.

The `castNameOrNum` argument can be either a string that specifies the name of the movie to access or an integer that specifies the number of the movie to access.

This property provides functionality similar to the top level `castLib()` method, except that the `castLib()` method applies only to the currently active movie.

**Example**

This statement displays the number of the Buttons cast in the Message window.

```plaintext
-- Lingo syntax
put(_movie.castLib["Buttons"].number)

// JavaScript syntax
put(_movie.castLib["Buttons"].number);
```

**See also**

castLib(), Movie
**castLibNum**

**Usage**

-- Lingo syntax
memberObjRef.castLibNum

// JavaScript syntax
memberObjRef.castLibNum;

**Description**

Member property; determines the number of the cast library that a cast member belongs to. Read-only.

**Example**

This statement determines the number of the cast to which cast member Jazz is assigned.

-- Lingo syntax
put(member("Jazz").castLibNum)

// JavaScript syntax
put(member("Jazz").castLibNum);

The following statement changes the cast member assigned to sprite 5 by switching its cast to Wednesday Schedule.

-- Lingo syntax
sprite(5).castLibNum = castLib("Wednesday Schedule").number

// JavaScript syntax
sprite(5).castLibNum = castLib("Wednesday Schedule").number;

**See also**

Cast Library, Member

---

**castMemberList**

**Usage**

-- Lingo syntax
memberObjRef.castMemberList

// JavaScript syntax
memberObjRef.castMemberList;

**Description**

Cursor cast member property; specifies a list of cast members that make up the frames of a cursor. For `whichCursorCastMember`, substitute a cast member name (within quotation marks) or a cast member number. You can also specify cast members from different casts.

The first cast member in the list is the first frame of the cursor, the second cast member is the second frame, and so on.

If you specify cast members that are invalid for use in a cursor, they will be ignored, and the remaining cast members will be used.

This property can be tested and set.
Example

This command sets a series of four cast members for the animated color cursor cast member named myCursor.

-- Lingo syntax
member("myCursor").castmemberList = \
   [member(1), member(2), member(1, 2), member(2, 2)]

// JavaScript syntax
member("myCursor").castmemberList = 
   list(member(1), member(2), member(1, 2), member(2, 2));

center

Usage

member(whichCastMember).center
the center of member whichCastMember

Description

Cast member property; interacts with the crop cast member property.

• When the crop property is FALSE, the center property has no effect.
• When crop is TRUE and center is TRUE, cropping occurs around the center of the digital video cast member.
• When crop is TRUE and center is FALSE, the digital video's right and bottom sides are cropped.

This property can be tested and set.

Example

This statement causes the digital video cast member Interview to be displayed in the top left corner of the sprite.

Dot syntax:
member("Interview").center = FALSE

Verbose syntax:
set the center of member "Interview" to FALSE

See also

crop, centerRegPoint, regPoint, scale (Member)
centerRegPoint

Usage

-- Lingo syntax
memberObjRef.centerRegPoint

// JavaScript syntax
memberObjRef.centerRegPoint;

Description

Flash, vector shape, and bitmap cast member property; automatically centers the registration point of the cast member when you resize the sprite (TRUE, default); or repositions the registration point at its current point value when you resize the sprite, set the defaultRect property, or set the regPoint property (FALSE).

This property can be tested and set.

Example

This script checks to see if a Flash movie's centerRegPoint property is set to TRUE. If it is, the script uses the regPoint property to reposition the sprite's registration point to its upper left corner. By checking the centerRegPoint property, the script ensures that it does not reposition a registration point that had been previously set using the regPoint property.

-- Lingo syntax
property spriteNum

on beginSprite me
  if sprite(spriteNum).member.centerRegPoint = TRUE then
    sprite(spriteNum).member.regPoint = point(0,0)
  end if
end

// JavaScript syntax
function beginSprite() {
  var ctrRg = sprite(this.spriteNum).member.centerRegPoint;
  if (ctrRg = 1) {
    sprite(this.spriteNum).member.regPoint = point(0,0);
  }
}

See also

regPoint

centerStage

Usage

-- Lingo syntax
_movie.centerStage

// JavaScript syntax
_movie.centerStage;

Description

Movie property; determines whether the Stage is centered on the monitor when the movie is loaded (TRUE, default) or not centered (FALSE). Read/write.
Place the statement that includes this property in the movie that precedes the movie you want it to affect.

This property is useful for checking the Stage location before a movie plays from a projector.

**Note:** Be aware that behavior while playing back in a projector differs between Windows and Macintosh systems. Settings selected during creation of the projector may override this property.

**Example**

This statement sends the movie to a specific frame if the Stage is not centered:

```-- Lingo syntax
if (_movie.centerStage = FALSE) then
   _movie.go("Off Center")
end if

// JavaScript syntax
if (_movie.centerStage == false) {
   _movie.go("Off Center");
}
```

This statement changes the `centerStage` property to the opposite of its current value:

```-- Lingo syntax
_movie.centerStage = not(_movie.centerStage)

// JavaScript syntax
_movie.centerStage = !_movie.centerStage
```

**See also**

`fixStageSize`, `Movie`

### changeArea

**Usage**

```member(whichCastMember).changeArea
```

**Description**

Transition cast member property; determines whether a transition applies only to the changing area on the Stage (TRUE) or to the entire Stage (FALSE). Its effect is similar to selecting the Changing Area Only option in the Frame Properties Transition dialog box.

This property can be tested and set.

**Example**

This statement makes the transition cast member Wave apply only to the changing area on the Stage.

**Dot syntax:**

```member("Wave").changeArea = TRUE```

**Verbose syntax:**

```set the changeArea of member "Wave" to TRUE```
channelCount

Usage

-- Lingo syntax
soundChannelObjRef.channelCount

// JavaScript syntax
soundChannelObjRef.channelCount;

Description

Sound Channel property; determines the number of channels in the currently playing or paused sound in a given sound channel. Read-only.

This property is useful for determining whether a sound is in monaural or in stereo.

Example

This statement determines the number of channels in the sound cast member, Jazz.

-- Lingo syntax
put(member("Jazz").channelCount)

// JavaScript syntax
put(member("Jazz").channelCount);

This statement determines the number of channels in the sound member currently playing in sound channel 2:

-- Lingo syntax
put(sound(2).channelCount)

// JavaScript syntax
put(sound(2).channelCount);

See also

Sound Channel

chapter

Usage

-- Lingo syntax
dvdObjRef.chapter

// JavaScript syntax
dvdObjRef.chapter;

Description

DVD property; returns the number of the current chapter. Read/write.

Example

This statement returns the current chapter.

-- Lingo syntax
trace (member(1).chapter) -- 1

// JavaScript syntax
trace (member(1).chapter); // 1

See also

DVD
chapterCount

Usage
-- Lingo syntax
dvdObjRef.chapterCount

// JavaScript syntax
dvdObjRef.chapterCount;

Description
DVD property; returns the number of available chapters in a title. Read-only.

See also
chapterCount(), DVD

characterSet

Usage
-- Lingo syntax
memberObjRef.characterSet

// JavaScript syntax
memberObjRef.characterSet;

Description
Font cast member property; returns a string containing the characters included for import when the cast member was created. If all characters in the original font were included, the result is an empty string.

Example
This statement displays the characters included when cast member 11 was created. The characters included during import were numerals and Roman characters.

-- Lingo syntax
put(member(11).characterSet)

// JavaScript syntax
put(member(11).characterSet);

See also
recordFont, bitmapSizes, originalFont

ccharSpacing

Usage
-- Lingo syntax
chunkExpression.charSpacing

// JavaScript syntax
chunkExpression.charSpacing;

Description
Text cast member property; enables specifying any additional spacing applied to each letter in the chunkExpression portion of the text cast member.
A value less than 0 indicates less spacing between letters. A value greater than 0 indicates more spacing between letters.

The default value is 0, which results in default spacing between letters.

**Example**

The following handler increases the current character spacing of the third through fifth words within the text cast member myCaption by a value of 2:

```lingo
-- Lingo syntax
on myCharSpacer
    mySpaceValue = member("myCaption").word[3..5].charSpacing
    member("myCaption").word[3..5].charSpacing = (mySpaceValue + 2)
end

// JavaScript syntax
function myCharSpacer() {
    var i = 3;
    while (i < 6) {
        var mySpaceValue = member("myCaption").getPropRef("word", i).charSpacing;
        member("myCaption").getPropRef("word", i).charSpacing = (mySpaceValue + 2);
    }
}
```

**checkMark**

**Usage**

the checkMark of menuItem whichItem of menu whichMenu

**Description**

Menu item property; determines whether a check mark appears next to the custom menu item (TRUE) or not (FALSE, default).

The `whichItem` value can be either a menu item name or a menu item number. The `whichMenu` value can be either a menu name or a menu number.

This property can be tested and set.

*Note:* Menus are not available in Shockwave Player.

**Example**

This handler turns off any items that are checked in the custom menu specified by the argument `theMenu`. For example, `unCheck ("Format")` turns off all the items in the Format menu.

```lingo
on unCheck theMenu
    set n = the number of menuItems of menu theMenu
    repeat with i = 1 to n
        set the checkMark of menuItem i of menu theMenu to FALSE
    end repeat
end unCheck
```

**See also**

`installMenu`, `enabled`, `name (menu item property)`, `number (menu items)`, `script`, `menu`
child (3D)

Usage

member(whichCastmember).model(whichParentNode).child(whichChildNodeName)
member(whichCastmember).model(whichParentNode).child[index]

Description

3D model, group, light, and camera property; returns the child node named
whichChildNodeName or at the specified index in the parent node's list of children. A node is a
model, group, camera, or light.

The transform of a node is parent-relative. If you change the position of the parent, its children
move with it, and their positions relative to the parent are maintained. Changes to the rotation
and scale properties of the parent are similarly reflected in its children.

Use the addChild method of the parent node or set the parent property of the child node to add
to the parent's list of children. A child can have only one parent, but a parent can have any
number of children. A child can also have children of its own.

Example

This statement shows that the second child of the model named Car is the model named Tire.

put member("3D").model("Car").child[2] -- model("Tire")

See also

addChild, parent

child (XML)

Usage

XMLnode.child[childNumber]

Description

XML property; refers to the specified child node of a parsed XML document's nested
tag structure.

Example

Beginning with the following XML:

```xml
<?xml version="1.0"?>
<el>
  <tagName attr1="val1" attr2="val2"/>
  <e2>element 2</e2>
  <e3>element 3</e3>
  here is some text
</el>
```

This Lingo returns the name of the first child node of the preceding XML:

put gParserObject.child[1].name
-- "el"
chunkSize

Usage
member(\textit{whichCastMember}).\textit{chunkSize}
the \textit{chunkSize} of member \textit{whichCastMember}

Description
Transition cast member property; determines the transition's chunk size in pixels from 1 to 128 and is equivalent to setting the smoothness slider in the Frame Properties: Transition dialog box. The smaller the chunk size, the smoother the transition appears.

This property can be tested and set.

Example
This statement sets the chunk size of the transition cast member Fog to 4 pixels.

Dot syntax:
\text{member("Fog").chunkSize = 4}

Verbose syntax:
set the \text{chunkSize} of member \text{"Fog"} to 4

clearAtRender

Usage
member(\textit{whichCastmember}).camera(\textit{whichCamera}).colorBuffer.\textit{clearAtRender}
sprite(\textit{whichSprite}).camera(\textit{index}).colorBuffer.clearAtRender

Description
3D property; indicates whether the color buffer is cleared after each frame. Setting the value to false, which means the buffer is not cleared, gives an effect similar to trails ink effect. The default value for this property is true.

Example
This statement prevents Director from erasing past images of the view from the camera. Models in motion will appear to smear across the stage.

\text{sprite(1).camera.colorBuffer.clearAtRender = 0}

See also
clearValue
clearValue

**Usage**

```
member(whichCastmember).camera(whichCamera).colorBuffer.clearValue
sprite(whichSprite).camera(index).colorBuffer.clearValue
```

**Description**

3D property; specifies the color used to clear out the color buffer if `colorBuffer.clearAtRender` is set to `TRUE`. The default setting for this property is `rgb(0, 0, 0)`.

**Example**

This statement sets the `clearValue` property of the camera to `rgb(255, 0, 0)`. Spaces in the 3D world which are not occupied by models will appear red.

```
sprite(1).camera.colorBuffer.clearValue = rgb(255, 0, 0)
```

**See also**

`clearAtRender`

clickLoc

**Usage**

```
-- Lingo syntax
_mouse.clickLoc

// JavaScript syntax
_mouse.clickLoc;
```

**Description**

Mouse property; identifies as a point the last place on the screen where the mouse was clicked. Read-only.

**Example**

The following `on mouseDown` handler displays the last mouse click location:

```
-- Lingo syntax
on mouseDown
   put(_mouse.clickLoc)
end mouseDown

// JavaScript syntax
function mouseDown() {
   put(_mouse.clickLoc);
}
```

If the click were 50 pixels from the left end of the Stage and 100 pixels from the top of the Stage, the Message window would display the following:

```
point(50, 100)
```

**See also**

`clickOn`, `Mouse`
**clickMode**

**Usage**

-- Lingo syntax
memberOrSpriteObjRef.clickMode

// JavaScript syntax
memberOrSpriteObjRef.clickMode;

**Description**

Flash cast member and sprite property; controls when the Flash movie sprite detects mouse click events (mouseUp and mouseDown) and when it detects rollovers (mouseEnter, mouseWithin, and mouseLeave). The clickMode property can have these values:

- **#boundingBox**—Detects mouse click events anywhere within the sprite's bounding rectangle and detects rollovers at the sprite's boundaries.
- **#opaque** (default)—Detects mouse click events only when the pointer is over an opaque portion of the sprite and detects rollovers at the boundaries of the opaque portions of the sprite if the sprite's ink effect is set to Background Transparent. If the sprite's ink effect is not set to Background Transparent, this setting has the same effect as #boundingBox.
- **#object**—Detects mouse click events when the mouse pointer is over any filled (nonbackground) area of the sprite and detects rollovers at the boundaries of any filled area. This setting works regardless of the sprite's ink effect.

This property can be tested and set.

**Example**

This script checks to see if the sprite, which is specified with an ink effect of Background Transparent, is currently set to be rendered direct to Stage. If the sprite is not rendered direct to Stage, the sprite's `clickMode` is set to #opaque. Otherwise (because ink effects are ignored for Flash movie sprites that are rendered direct to Stage), the sprite's `clickMode` is set to #boundingBox.

-- Lingo syntax
property spriteNum

on beginSprite me
  if sprite(spriteNum).directToStage = FALSE then
    sprite(spriteNum).clickMode = #opaque
  else
    sprite(spriteNum).clickMode = #boundingBox
  end if
end

// JavaScript syntax
function beginSprite(me){
  var dts = sprite(this.spriteNum).directToStage;
  if (dts = 0) {
    sprite(this.spriteNum).clickMode = symbol("opaque");
  } else {
    sprite(this.spriteNum).clickMode = symbol("boundingBox");
  }
}
clickOn

Usage

-- Lingo syntax
_mouse.clickOn

// JavaScript syntax
_mouse.clickOn;

Description

Mouse property; returns the last active sprite clicked by the user. Read-only.

An active sprite is a sprite that has a sprite or cast member script associated with it.

When the user clicks the Stage, clickOn returns 0. To detect whether the user clicks a sprite with no script, you must assign a mouse event script to it so that it can be detected by clickOn. For example:

-- Lingo syntax
on mouseUp me
  ...
end

Buttons, check boxes, and radio buttons are detected by clickOn even if there is no script attached to them.

The clickOn property can be checked within a loop. However, neither clickOn nor clickLoc change value when the handler is running. The value that you obtain is the value from before the handler started.

Example

This statement checks whether sprite 7 was the last active sprite clicked:

-- Lingo syntax
if (_mouse.clickOn = 7) then
  _player.alert("Sorry, try again.")
end if

// JavaScript syntax
if (_mouse.clickOn = 7) {
  _player.alert("Sorry, try again.");
}

This statement sets the foreColor property of the last active sprite that was clicked to a random color:

-- Lingo syntax
sprite(_mouse.clickOn).foreColor = (random(255) - 1)

// JavaScript syntax
sprite(_mouse.clickOn).foreColor = (random(255) - 1);

See also

clickLoc, Mouse
closed

Usage
-- Lingo syntax
memberObjRef.closed

// JavaScript syntax
memberObjRef.closed;

Description
Vector shape cast member property; indicates whether the end points of a path are closed or open.
Vector shapes must be closed in order to contain a fill.
The value can be as follows:
• TRUE—the end points are closed.
• FALSE—the end points are open.

closedCaptions

Usage
-- Lingo syntax
dvdObjRef.closedCaptions

// JavaScript syntax
dvdObjRef.closedCaptions;

Description
DVD property. Determines whether closed captioning is enabled (TRUE), or if it is not or could not be enabled (FALSE). Currently unsupported on the Macintosh. Read/write.

Example
These statements try to set closedCaptions to TRUE, and display an alert if they cannot be enabled:

-- Lingo syntax
member(3).closedCaptions = TRUE
if (member(3).closedCaptions = FALSE) then
    _player.alert("Closed captions cannot be enabled.");
end if

// JavaScript syntax
member(3).closedCaptions = true
if (member(3).closedCaptions == false) {
    _player.alert("Closed captions cannot be enabled.");
}

See also
DVD
collision (modifier)

Usage

```javascript
member(whichCastmember).model(whichModel).\n  collision.collisionModifierProperty
```

Description

3D modifier; manages the detection and resolution of collisions. Adding the collision modifier to a model by using the addModifier command allows access to the following collision modifier properties:

- **enabled (collision)** indicates whether collisions with the model are detected.
- **resolve** indicates whether collisions with the model are resolved.
- **immovable** indicates whether a model can be moved from frame to frame.
- **mode (collision)** indicates the geometry used for collision detection.

**Note:** For more detailed information about these properties, see the individual property entries.

The collision modifier generates the following events. For more information about using collision events, see the `registerForEvent()` entry.

A `#collideAny` event is generated when a collision occurs between models to which the collision modifier has been attached.

A `#collideWith` event is generated when a collision occurs with a specific model to which the collision modifier has been attached.

The `collisionData` object is sent as an argument with the `#collideAny` and `#collideWith` events. See the `collisionData` entry for details of its properties.

See also

`addModifier`, `removeModifier`, `modifiers`

collisionData

Usage

```javascript
on myHandlerName me, collisionData
```

Description

3D data object; sent as an argument with the `#collideWith` and `#collideAny` events to the handler specified in the `registerForEvent`, `registerScript`, and `setCollisionCallback` commands. The `collisionData` object has these properties:

- **modelA** is one of the models involved in the collision.
- **modelB** is the other model involved in the collision.
- **pointOfContact** is the world position of the collision.
- **collisionNormal** is the direction of the collision.
Example

This example has three parts. The first part is the first line of code, which registers the #putDetails handler for the #collideAny event. The second part is the #putDetails handler. When two models in the cast member MyScene collide, the #putDetails handler is called and the collisionData argument is sent to it. This handler displays the four properties of the collisionData object in the message window. The third part of the example shows the results from the message window. The first two lines show that the model named GreenBall was model A and the model named YellowBall was model B in the collision. The third line shows the point of contact of the two models. The last line shows the direction of the collision.

```lark
member("MyScene").registerForEvent(#collideAny, #putDetails, 0)

on putDetails me, collisionData
    put collisionData.modelA
    put collisionData.modelB
    put collisionData.pointOfContact
    put collisionData.collisionNormal
end

-- model("GreenBall")
-- model("YellowBall")
-- vector( 24.800, 0.000, 0.000 )
-- vector( -1.000, 0.000, 0.000 )
```

See also

collisionData properties: modelA, modelB, pointOfContact, collisionNormal

collisionData methods: resolveA, resolveB, collision (modifier)

collisionNormal

Usage

collisionData.collisionNormal

Description

3D collisionData property; a vector indicating the direction of the collision.

The collisionData object is sent as an argument with the #collideWith and #collideAny events to the handler specified in the registerForEvent, registerScript, and setCollisionCallback commands.

The #collideWith and #collideAny events are sent when a collision occurs between models to which collision modifiers have been added. The resolve property of the models' modifiers must be set to TRUE.

This property can be tested but not set.
Example

This example has two parts. The first part is the first line of code, which registers the `#explode` handler for the `#collideAny` event. The second part is the `#explode` handler. When two models in the cast member named MyScene collide, the `#explode` handler is called and the `collisionData` argument is sent to it. The first ten lines of the `#explode` handler create the model resource SparkSource and set its properties. This model resource is a single burst of particles. The tenth line sets the direction of the burst to `collisionNormal`, which is the direction of the collision. The eleventh line of the handler creates a model called SparksModel using the model resource SparkSource. The last line of the handler sets the position of SparksModel to the position where the collision occurred. The overall effect is a collision that causes a burst of sparks to fly in the direction of the collision from the point of contact.

```plaintext
member("MyScene").registerForEvent(#collideAny. #explode, 0)
on explode me, collisionData
  nmr = member("MyScene").newModelResource("SparkSource", #particle)
  nmr.emitter.mode = #burst
  nmr.emitter.loop = 0
  nmr.emitter.minSpeed = 30
  nmr.emitter.maxSpeed = 50
  nmr.emitter.angle = 45
  nmr.colorRange.start = rgb(0, 0, 255)
  nmr.colorRange.end = rgb(255, 0, 0)
  nmr.emitter.direction = vector(0,0,-1)
  nm = member("MyScene").newModel("SparksModel", nmr)
  nm.transform.position = collisionData.pointOfContact
  nm.pointAt(collisionData.pointOfContact + collisionData.collisionNormal)
end
```

See also

- `pointOfContact`, `modelA`, `modelB`, `resolveA`, `resolveB`, `collision` (modifier)
- `color()`

**color()**

**Usage**

- `color(#rgb, redValue, greenValue, blueValue)`
- `color(#paletteIndex, paletteIndexNumber)`
- `rgb(rgbHexString)`
- `rgb(redValue, greenValue, blueValue)`
- `paletteIndex(paletteIndexNumber)`

**Description**

Function and data type; determines an object's color as either RGB or 8-bit palette index values. These are the same values as those used in the `color` member and `color` sprite properties, the `bgColor` member and `bgColor` sprite properties, and the `bgColor` Stage property.

The `color` function allows for either 24-bit or 8-bit color values to be manipulated as well as applied to cast members, sprites, and the Stage.

For RGB values, each color component has a range from 0 to 255, and all other values are truncated. For paletteIndex types, an integer from 0 to 255 is used to indicate the index number in the current palette, and all other values are truncated.
Example

This statement performs a math operation:

```lingo
palColorObj = paletteIndex(20)
put palColorObj
-- paletteIndex(20)
palColorObj / 2
-- paletteIndex(10)
```

This statement converts one color type to another type:

```lingo
newColorObj = color(#rgb, 155, 0, 75)
put newColorObj
-- rgb(155, 0, 75)
newColorObj.colorType = #paletteIndex
put newColorObj
-- paletteIndex(106)
```

This statement obtains the hexadecimal representation of a color regardless of its type:

```lingo
someColorObj = color(#paletteIndex, 32)
put someColorObj.hexString()
-- "#FF0099"
```

This statement determines individual RGB components and the `paletteIndex` value of a color regardless of its type:

```lingo
newColorObj = color(#rgb, 155, 0, 75)
pic newColorObj.green
-- 0
put newColorObj.paletteIndex
-- 106
newColorObj.green = 100
put newColorObj.paletteIndex
-- 94
put newColorObj
-- rgb(155, 100, 75)
newColorObj.paletteIndex = 45
put newColorObj
-- paletteIndex(45)
```

This statement changes the color of the fourth through the seventh characters of text member `myQuotes`:

```lingo
member("myQuotes").char[4..7].color = rgb(200, 150, 75)
```

This Lingo displays the color of sprite 6 in the Message window, and then sets the color of sprite 6 to a new RGB value:

```lingo
put sprite(6).color
-- rgb(255, 204, 102)
sprite(6).color = rgb(122, 98, 210)
```

**Note:** Setting the `paletteIndex` value of an RGB color type changes the `colorType` to `paletteIndex`. Setting the RGB color type of a `paletteIndex` color sets its `colorType` value to RGB.

See also

- `bgColor (Window)`
**color (fog)**

**Usage**
```
member(whichCastmember).camera(whichCamera).fog.color
sprite(whichSprite).camera(index).fog.color
```

**Description**
3D property; indicates the color introduced into the scene by the camera when the camera's `fog.enabled` property is set to TRUE.

The default setting for this property is `rgb(0, 0, 0)`.

**Example**
This statement sets the color of the fog of the camera named BayView to `rgb(255, 0, 0)`. If the camera's `fog.enabled` property is set to TRUE, models in the fog will take on a red hue.
```
member("MyYard").camera("BayView").fog.color = rgb(255, 0, 0)
```

**See also**
`fog`

**color (light)**

**Usage**
```
member(whichCastmember).light(whichLight).color
```

**Description**
3D light property; indicates the rgb value of the light.

The default value of this property is `rgb(191,191,191)`.

**Example**
This statement sets the color of the light named RoomLight to `rgb(255, 0, 255)`.
```
member("Room").light("RoomLight").color = rgb(255,0,255)
```

**See also**
`fog`

**colorBufferDepth**

**Usage**
```
getRendererServices().colorBufferDepth
```

**Description**
3D `rendererServices` property; indicates the color precision of the hardware output buffer of the user's system. The value is either 16 or 32, depending on the user's hardware settings.

This property can be tested but not set.
Example

This statement shows that the colorBufferDepth value of the user's video card is 32.

put getRendererServices().colorBufferDepth
-- 32

See also

getRendererServices(), getHardwareInfo(), depthBufferDepth

colorDepth

Usage

-- Lingo syntax
_system.colorDepth

// JavaScript syntax
_system.colorDepth;

Description

System property; determines the color depth of the computer's monitor. Read/write.

- In Windows, using this property lets you check and set the monitor's color depth. Some video card and driver combinations may not enable you to set the colorDepth property. Always verify that the color depth has actually changed after you attempt to set it.
- On the Macintosh, this property lets you check the color depth of different monitors and change it when appropriate.

Possible values are the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Black and white</td>
</tr>
<tr>
<td>2</td>
<td>4 colors</td>
</tr>
<tr>
<td>4</td>
<td>16 colors</td>
</tr>
<tr>
<td>8</td>
<td>256 colors</td>
</tr>
<tr>
<td>16</td>
<td>32,768 or 65,536 colors</td>
</tr>
<tr>
<td>32</td>
<td>16,777,216 colors</td>
</tr>
</tbody>
</table>

If you try to set a monitor's color depth to a value that monitor does not support, the monitor's color depth doesn't change.

On computers with more than one monitor, the colorDepth property refers to the monitor displaying the Stage. If the Stage spans more than one monitor, the colorDepth property indicates the greatest depth of those monitors; colorDepth tries to set all those monitors to the specified depth.
Example

This statement tells Director to open the movie Full color only if the monitor color depth is set to 256 colors:

-- Lingo syntax
if (_system.colorDepth = 8) then
    window("Full color").open()
end if

// JavaScript syntax
if (_system.colorDepth == 8) {
    window("Full color").open();
}

The following handler tries to change the color depth, and if it can't, it displays an alert:

-- Lingo syntax
on tryToSetColorDepth(desiredDepth)
    _system.colorDepth = desiredDepth
    if (_system.colorDepth = desiredDepth) then
        return true
    else
        _player.alert("Please change your system to" && desiredDepth && "color depth and reboot.");
        return false
    end if
end

// JavaScript syntax
function tryToSetColorDepth(desiredDepth) {
    _system.colorDepth = desiredDepth;
    if (_system.colorDepth == desiredDepth) {
        return true;
    } else {
        _player.alert("Please change your system to " + desiredDepth + " color depth and reboot.");
        return false;
    }
}

See also

System
colorList

Usage

member(whichCastmember).modelResource(whichModelResource).\colorList
member(whichCastmember).modelResource(whichModelResource).\colorList[index]
member(whichCastmember).model(whichModel).meshdeform.mesh\[meshIndex].colorList
member(whichCastmember).model(whichModel).meshdeform.mesh\[meshIndex].colorList[index]
**Description**

3D property; allows you to get or set every color used in a mesh. This command is accessible only for model resources of the type #mesh. Any single color can be shared by several vertices (faces) of the mesh. Alternately, you can specify texture coordinates for the faces of the mesh and apply a shader to models that use this model resource.

This command must be set to a list of the same number of Lingo color values specified in the `newMesh` call.

**Example**

This statement shows that the third color in the colorList of the model resource Mesh2 is rgb(255, 0, 0).

```lisp
put member("shapes").modelResource("mesh2").colorlist[3] -- rgb(255,0,0)
```

**See also**

`face[ ], colors`

**colorRange**

**Usage**

```lisp
member(whichCastmember).modelResource(whichModelResource).\colorRange.start
member(whichCastmember).modelResource(whichModelResource).\colorRange.end
```

**Description**

3D #particle model resource properties; indicate the beginning color and ending color of the particles of a particle system.

The `start` property is the color of the particles when they are created. The `end` property is the color of particles at the end of their lives. The color of each particle gradually changes from the value of `start` to the value of `end` over the course of its life.

The `start` and `end` properties have a default value of rgb(255, 255, 255).

**Example**

This statement sets the `colorRange` properties of the model resource named ThermoSystem. The first line sets the `start` value to rgb(255, 0, 0), and the second line sets the `end` value to rgb(0, 0, 255). The effect of this statement is that the particles of ThermoSystem are red when they first appear, and gradually change to blue during their lifetimes.

```lisp
member(8,2).modelResource("ThermoSystem").colorRange.start = rgb(255,0,0)
member(8,2).modelResource("ThermoSystem").colorRange.end = rgb(0,0,255)
```

**See also**

`emitter, blendRange, sizeRange`
colors

Usage

member(whichCastmember).modelResource(whichModelResource).\n  face[faceIndex].colors

Description

3D face property; a linear list of three integers indicating which index positions of the model resource's color list to use for the three vertices of the face. The color list is a linear list of rgb values.

The colors property is used only with model resources whose type is #mesh.

You must use the model resource's build() command after setting this property; otherwise, the changes will not take effect.

Example

This example creates a model resource whose type is #mesh, specifies its properties, and then creates a new model with it.

Line 1 uses the newMesh() command to create a #mesh model resource named Triangle, which has one face, three vertices, and a maximum of three colors. The number of normals and the number of texture coordinates are not set.

Line 2 sets the vertexList property to a list of three vectors.

Line 3 assigns the vectors of the vertexList property to the vertices of the first face of Triangle.

Line 4 sets the color list to three rgb values.

Line 5 assigns colors to the first face of Triangle. The third color in the color list is applied to the first vertex of Triangle, the second color to the second vertex, and the first color to the third vertex. The colors will spread across the first face of Triangle in gradients.

Line 6 creates the normals of Triangle with the generateNormals() command.

Line 7 uses the build() command to construct the mesh.

Line 8 creates a new model named TriModel that uses the new mesh.

```
nm = member("Shapes").newMesh("Triangle",1,3,0,3,0)
nm.vertexList = [vector(0,0,0), vector(20,0,0), vector(20, 20, 0)]
nm.face[1].vertices = [1,2,3]
nm.colorList = [rgb(255,255,0), rgb(0, 255, 0), rgb(0,0,255)]
nm.face[1].colors = [3,2,1]
nm.generateNormals(#smooth)
nm.build()
nm = member("Shapes").newModel("TriModel", nm)
```

See also

face, vertices, vertices, flat
colorSteps

Usage

member(whichCastmember).model(whichModel).toon.colorSteps
member(whichCastmember).model(whichModel).shader.colorSteps
member(whichCastmember).shader(whichShader).colorSteps

Description

3D toon modifier and painter shader property; the maximum number of colors available for use by the toon modifier or painter shader. The value of this property can be 2, 4, 8, or 16. If you set the value of colorSteps to any other number, it will be rounded to one of these.

The default value is 2.

Example

This statement limits the number of colors available for use by the toon modifier for the model named Teapot to 8. The teapot will be rendered with a maximum of eight colors.

member("shapes").model("Teapot").toon.colorSteps = 8

See also

highlightPercentage, shadowPercentage

commandDown

Usage

-- Lingo syntax
_key.commandDown
// JavaScript syntax
_key.commandDown;

Description

Key property; determines whether the Control key (Windows) or the Command key (Macintosh) is being pressed. Read-only.

This property returns TRUE if the Control or Command key is being pressed; otherwise, it returns FALSE.

You can use commandDown together with the key property to determine whether the Control or Command key is being pressed in combination with another key. This lets you create handlers that are executed when the user presses specified Control or Command key combinations.

Control or Command key equivalents for the Director authoring menus take precedence while the movie is playing, unless you have installed custom Lingo or JavaScript syntax menus or are playing a projector version of the movie.
Example

These statements pause a projector when the playhead enters a frame and the user is pressing Control+A (Windows) or Command+A (Macintosh).

```-- Lingo syntax
on enterFrame
  if (_key.commandDown and _key.key = "a") then
    _movie.go(_movie.frame)
  end if
end
```

```// JavaScript syntax
function enterFrame() {
  if (_key.commandDown && _key.key == "a") {
    _movie.go(_movie.frame);
  }
}
```

See also

Key, key

comments

Usage

```-- Lingo syntax
memberObjRef.comments
```

```// JavaScript syntax
memberObjRef.comments;
```

Description

Member property; provides a place to store any comments you want to maintain about the given cast member or any other strings you want to associate with the member. Read/write.

This property can also be set in the Property inspector’s Member tab.

Example

This statement sets the comments of the member Backdrop to the string “Still need to license this artwork”:

```-- Lingo syntax
member("Backdrop").comments = "Still need to license this artwork"
```

```// JavaScript syntax
member("Backdrop").comments = "Still need to license this artwork";
```

See also

Member
**compressed**

**Usage**

```lingo
member(whichCastmember).texture(whichTexture).compressed
```

**Description**

3D texture property; indicates whether the source cast member of the texture is compressed (TRUE) or not (FALSE). The value of the `compressed` property changes automatically from TRUE to FALSE when the texture is needed for rendering. It can be set to FALSE to decompress the texture at an earlier time. It can be set to TRUE to release the decompressed representation from memory. Cast members used for textures will not be compressed if this value is TRUE (apart from the standard compression used for bitmap cast members when a Director movie is saved). The default value for this property is TRUE.

**Example**

This statement sets the `compressed` property of the texture Plutomap to TRUE.

```lingo
member("scene").texture("Plutomap").compressed = TRUE
```

**See also**

`texture`

**constraint**

**Usage**

```lingo
-- Lingo syntax
spriteObjRef.constraint
```

```javascript
// JavaScript syntax
spriteObjRef.constraint;
```

**Description**

Sprite property; determines whether the registration point of a sprite is constrained to the bounding rectangle of another sprite (1 or TRUE) or not (0 or FALSE, default). Read/write.

The `constraint` property is useful for constraining a moveable sprite to the bounding rectangle of another sprite to simulate a track for a slider control or to restrict where on the screen a user can drag an object in a game.

The `constraint` property affects moveable sprites and the `locH` and `locV` properties. The constraint point of a moveable sprite cannot be moved outside the bounding rectangle of the constraining sprite. (The constraint point for a bitmap sprite is the registration point. The constraint point for a shape sprite is its top left corner.) When a sprite has a constraint set, the constraint limits override any `locH` and `locV` property settings.
Example

This statement removes a constraint sprite property:

-- Lingo syntax
sprite(5).constraint = 0

// JavaScript syntax
sprite(5).constraint = 0;

This statement constrains sprite (i + 1) to the boundary of sprite 14:

-- Lingo syntax
sprite(i + 1).constraint = 14

// JavaScript syntax
sprite(i + 1).constraint = 14;

This statement checks whether sprite 3 is constrained and activates the handler showConstraint if it is:

-- Lingo syntax
if (sprite(3).constraint <> 0) then
  showConstraint
end if

// JavaScript syntax
if (sprite(3).constraint != 0) {
  showConstraint();
}

See also
locH, locV, Sprite

controlDown

Usage

-- Lingo syntax
_key.controlDown

// JavaScript syntax
_key.controlDown;

Description

Key property; determines whether the Control key is being pressed. Read-only.

This property returns TRUE if the Control key is being pressed; otherwise, it returns FALSE.

You can use controlDown together with the key property to determine whether the Control key is being pressed in combination with another key. This lets you create handlers that are executed when the user presses specified Control key combinations.

Control or key equivalents for the Director authoring menus take precedence while the movie is playing, unless you have installed custom Lingo or JavaScript syntax menus or are playing a projector version of the movie.
Example

This on keyDown handler checks whether the pressed key is the Control key, and if it is, the handler activates the on doControlKey handler. The argument (_key.key) identifies which key was pressed in addition to the Control key.

```-- Lingo syntax
on keyDown
  if (_key.controlDown) then
    doControlKey(_key.key)
  end if
end

on doControlKey(theKey)
  trace("The " & theKey & " key is down")
end

// JavaScript syntax
function keyDown() {
  if (_key.controlDown) {
    doControlKey(_key.key);
  }
}

function doControlKey(theKey) {
  trace("The " & theKey & " key is down");
}
```

See also

Key, key

controller

Usage

```member(whichCastMember).controller```

the controller of member whichCastMember

Description

Digital video cast member property; determines whether a digital video movie cast member shows or hides its controller. Setting this property to 1 shows the controller; setting it to 0 hides the controller.

The controller member property applies to a QuickTime digital video only.

- Setting the controller member property for a Video for Windows digital video performs no operation and generates no error message.
- Checking the controller member property for a Video for Windows digital video always returns FALSE.

The digital video must be in direct-to-stage playback mode to display the controller.
Example
This statement causes the QuickTime cast member Demo to display its controller.

Dot syntax:
member("Demo").controller = 1

Verbose syntax:
set the controller of member "Demo" to 1

See also
directToStage

copyrightInfo (Movie)

Usage
-- Lingo syntax
_movie.copyrightInfo

// JavaScript syntax
_movie.copyrightInfo;

Description
Movie property; enters a string during authoring in the Movie Properties dialog box. This property is provided to allow for enhancements in future versions of Shockwave Player. Read-only.

See also
aboutInfo, Movie

copyrightInfo (SWA)

Usage
-- Lingo syntax
memberObjRef.copyrightInfo

// JavaScript syntax
memberObjRef.copyrightInfo;

Description
Shockwave Audio (SWA) cast member property; displays the copyright text in a SWA file. This property is available only after the SWA sound begins playing or after the file has been preloaded using the preLoadBuffer command.

This property can be tested and set.
Example

This statement tells Director to display the copyright information for the Shockwave Audio file SWAfile in a field cast member named Info Display.

-- Lingo syntax
whatState = member("SWAfile").state
if whatState > 1 AND whatState < 9 then
  put(member("Info Display") = member("SWAfile").copyrightInfo)
end if

// JavaScript syntax
var whatState = member("SWAfile").state;
if (whatState > 1 && whatState < 9) {
  put(member("Info Display") = member("SWAfile").copyrightInfo);
}

count

Usage

list.count
  count (list)
  count(theObject)
  object.count
  textExpression.count

Description

Property (Lingo only); returns the number of entries in a linear or property list, the number of properties in a parent script without counting the properties in an ancestor script, or the chunks of a text expression such as characters, lines, or words.

The count command works with linear and property lists, objects created with parent scripts, and the `globals` property.

To see an example of `count()` used in a completed movie, see the Text movie in the Learning/Lingo Examples folder inside the Director application folder.

Example

This statement displays the number 3, the number of entries:

put [10,20,30].count
-- 3

member(whichCastmember).camera(whichCamera).backdrop.count
sprite(whichSprite).camera(index).overlay.count
member(whichCastmember).camera(whichCamera).overlay.count
member(whichCastmember).model(whichModel).modifier.count
member(whichCastmember).model(whichModel).keyframePlayer.\ playlist.count
member(whichCastmember).model(whichModel).bonesPlayer.\ playlist.count
member(whichCastmember).modelResource(whichModelResource).\ face.count
member(whichCastmember).model(whichModel).meshDeform.\ mesh[index].textureLayer.count
member(whichCastmember).model(whichModel).meshDeform.mesh.count
member(whichCastmember).model(whichModel).meshDeform.\ mesh[index].face.count

Description

3D property; returns the number of items in the given list that is associated with the given 3D object. Can be used with any type of object.

The face.count property allows you to get the number of triangles in the mesh for a model resource whose type is #mesh.

This property can be tested but not set.

Example

These examples determine the number of various types of objects within a 3D cast member called 3D World.

numberOfCameras = member("3D World").camera.count
put member("3D World").light.count
-- 3
numberOfModels = member("3D World").model.count
numberOfTextures = member("3D World").texture.count
put member("3D World").modelResource("mesh2").face.count
-- 4

This statement shows that the first mesh of the model named Ear is composed of 58 faces.

put member("Scene").model("Ear").meshdeform.mesh[1].face.count
-- 58
This statement shows that the model named Ear is composed of three meshes.

```
put member("Scene").model("Ear").meshdeform.mesh.count
-- 3
```

This statement shows that the first mesh of the model named Ear has two texture layers.

```
put member("Scene").model("Ear").meshdeform.mesh[1].
  textureLayer.count
-- 2
```

See also

cameraCount() cpuHogTicks

Usage

```
the cpuHogTicks
```

Description

System property; determines how often Director releases control of the CPU to let the computer process background events, such as events in other applications, network events, clock updates, and other keyboard events.

The default value is 20 ticks. To give more time to Director before releasing the CPU to background events or to control how the computer responds to network operations, set `cpuHogTicks` to a higher value.

To create faster auto-repeating key performance but slower animation, set `cpuHogTicks` to a lower value. In a movie, when a user holds down a key to generate a rapid sequence of auto-repeating key presses, Director typically checks for auto-repeating key presses less frequently than the rate set in the computer's control panel.

The `cpuHogTicks` property works only on the Macintosh.

Example

This statement tells Director to release control of the CPU every 6 ticks, or every 0.10 of a second:

```
the cpuHogTicks = 6
```

See also

milliseconds

cpuHogTicks

cpuHogTicks

Usage

```
member(whichCastmember).model(whichModel).inker.creaseAngle
member(whichCastmember).model(whichModel).toon.creaseAngle
```

Description

3D `inker` and `toon` modifier property; indicates the sensitivity of the line drawing function of the modifier to the presence of creases in the model's geometry. Higher settings result in more lines (detail) drawn at creases.
The `creases` property of the modifier must be set to `TRUE` for the `creaseAngle` property to have an effect.

`CreaseAngle` has a range of -1.0 to +1.0. The default setting is 0.01.

**Example**

This statement sets the `creaseAngle` property of the `inker` modifier applied to the model named `Teapot` to 0.10. A line will be drawn at all creases in the model that exceed this threshold. This setting will only take effect if the `inker` modifier's `creases` property is set to `TRUE`.

```lingo
member("shapes").model("Teapot").inker.creaseAngle = 0.10
```

**See also**

creases, `lineColor`, `lineOffset`, `useLineOffset`

description: 3D `toon` and `inker` modifier property; determines whether lines are drawn at creases in the surface of the model.

The default setting for this property is `TRUE`.

**Example**

This statement sets the `creases` property of the `inker` modifier for the model named `Teapot` to `TRUE`. A line will be drawn on all creases in the model that exceed the threshold set by the `inker` modifier's `creaseAngle` property.

```lingo
member("shapes").model("Teapot").inker.creases = TRUE
```

**See also**

creaseAngle, `lineColor`, `lineOffset`, `useLineOffset`

description: `creationDate` member property; records the date that the cast member was first created by using the system date on the computer. Read-only.

You can use this property to schedule a project; Director does not use it for anything.
Example
Although you typically inspect the `creationDate` property using the Property inspector or the Cast window list view, you can check it in the Message window:

-- Lingo syntax
put(member(1).creationDate)

// JavaScript syntax
put(member(1).creationDate);

See also
Member

crop

Usage

member(whichCastMember).crop
the crop of member whichCastMember

Description
Cast member property; scales a digital video cast member to fit exactly inside the sprite rectangle in which it appears (FALSE), or it crops but doesn't scale the cast member to fit inside the sprite rectangle (TRUE).

This property can be tested and set.

Example

This statement instructs Lingo to crop any sprite that refers to the digital video cast member Interview.

Dot syntax:
member("Interview").crop = TRUE

Verbose syntax:
set the crop of member "Interview" to TRUE

center

cuePointNames

Usage

-- Lingo syntax
memberObjRef.cuePointNames

// JavaScript syntax
memberObjRef.cuePointNames;

Description
Cast member property; creates list of cue point names, or if a cue point is not named, inserts an empty string ("") as a placeholder in the list. Cue point names are useful for synchronizing sound, QuickTime, and animation.
This property is supported by SoundEdit cast members, QuickTime digital video cast members, and Xtra extension cast members that contain cue points. Xtra extensions that generate cue points at run time may not be able to list cue point names.

Example
This statement obtains the name of the third cue point of a cast member.

--- Lingo syntax
put member("symphony").cuePointNames[3]

// JavaScript syntax
put(member("symphony").cuePointNames[3]);

See also
cuePointNames, mostRecentCuePoint

cuePointTimes

Usage
--- Lingo syntax
memberObjRef.cuePointTimes

// JavaScript syntax
memberObjRef.cuePointTimes;

Description
Cast member property; lists the times of the cue points, in milliseconds, for a given cast member. Cue point times are useful for synchronizing sound, QuickTime, and animation.

This property is supported by SoundEdit cast members, QuickTime digital video cast members, and Xtra extension cast members that support cue points. Xtra extensions that generate cue points at run time may not be able to list cue point names.

Example
This statement obtains the time of the third cue point for a sound cast member.

--- Lingo syntax
put member("symphony").cuePointTimes[3]

// JavaScript syntax
put(member("symphony").cuePointTimes[3]);

See also
cuePointNames, mostRecentCuePoint
**currentLoopState**

**Usage**

```lingo
member(whichCastmember).model(whichModel).keyframePlayer.
currentLoopState
member(whichCastmember).model(whichModel).bonesPlayer.
currentLoopState
```

**Description**

3D keyframePlayer and bonesPlayer modifier property; indicates whether the motion being executed by the model repeats continuously (TRUE) or plays to the end and is replaced by the next motion in the modifier's playlist (FALSE).

The default setting for this property is the value of the looped parameter of the `play()` command that initiated playback of the motion, or the value of the `queue()` command that added the motion to the modifier's playlist. Changing the `currentLoopState` property also changes the value of the #looped property of the motion's entry in the modifier's playlist.

**Example**

This statement causes the motion that is being executed by the model named Monster to repeat continuously.

```lingo
member("NewAlien").model("Monster").keyframePlayer.
currentLoopState = TRUE
```

**See also**

`loop (3D), play() (3D), queue() (3D), playlist`

---

**currentSpriteNum**

**Usage**

```lingo
-- Lingo syntax
_player.currentSpriteNum

// JavaScript syntax
_player.currentSpriteNum;
```

**Description**

Player property; indicates the channel number of the sprite whose script is currently running. Read-only.

This property is valid in behaviors and cast member scripts. When used in frame scripts or movie scripts, the `currentSpriteNum` property's value is 0.

The `currentSpriteNum` property is similar to the Sprite object's `spriteNum` property.

**Note:** This property was more useful during transitions from older movies to Director 6, when behaviors were introduced. It allowed some behavior-like functionality without having to completely rewrite script. It is not necessary when authoring with behaviors and is therefore less useful than in the past.
Example

The following handler in a cast member or movie script switches the cast member assigned to the sprite involved in the mouseDown event:

-- Lingo syntax
on mouseDown
    sprite(_player.currentSpriteNum).member = member("DownPict")
end

// JavaScript syntax
function mouseDown() {
    sprite(_player.currentSpriteNum).member = member("DownPict");
}

See also
    Player, spriteNum

currentTime (3D)

Usage
    member(whichCastmember).model(whichModel).keyframePlayer.currentTime
    member(whichCastmember).model(whichModel).bonesPlayer.currentTime

Description

3D keyframePlayer and bonesPlayer modifier property; indicates the local time of the motion being executed by the model. The currentTime property is measured in milliseconds, but it only corresponds to real time when the motion is playing at its original speed.

Playback of a motion by a model is the result of either a play() or queue() command. The scale parameter of the play() or queue() command is multiplied by the modifier's playRate property, and the resulting value is multiplied by the motion's original speed to determine how fast the model will execute the motion and how fast the motion's local time will run. So if the scale parameter has a value of 2 and the modifier's playRate property has a value of 3, the model will execute the motion six times as fast as its original speed and local time will run six times as fast as real time.

The currentTime property resets to the value of the cropStart parameter of the play() or queue() command at the beginning of each iteration of a looped motion.

Example

This statement shows the local time of the motion being executed by the model named Alien3.

put member("newalien").model("Alien3").keyframePlayer.currentTime
   -- 1393.8599

See also
    play() (3D), queue() (3D), playlist
currentTime (DVD)

Usage
-- Lingo syntax
dvdObjRef.currentTime

// JavaScript syntax
dvdObjRef.currentTime;

Description
DVD property; returns the elapsed time, in milliseconds. Read/write.

Example
This statement returns the elapsed time:
-- Lingo syntax
trace (member(1).currentTime) -- 11500

// JavaScript syntax
trace (member(1).currentTime); // 11500

This statement sets currentTime to a specific point in the current title:
-- Lingo syntax
member(1).currentTime = 22000

// JavaScript syntax
member(1).currentTime = 22000

See also
DVD

currentTime (QuickTime, AVI)

Usage
-- Lingo syntax
spriteObjRef.currentTime

// JavaScript syntax
spriteObjRef.currentTime;

Description
Digital video sprite property; determines the current time of a digital video movie playing in the channel specified by whichSprite. The movieTime value is measured in ticks.

This property can be tested and set.

To see an example of currentTime used in a completed movie, see the QT and Flash movie in the Learning/Lingo Examples folder inside the Director application folder.

Example
This statement displays the current time of the QuickTime movie in channel 9 in the Message window:
-- Lingo syntax
put(sprite(9).currentTime)
This statement sets the current time of the QuickTime movie in channel 9 to the value in the variable "Poster":

-- Lingo syntax
sprite(9).currentTime = Poster

// JavaScript syntax
sprite(9).currentTime = Poster;

See also
duration (Member)

currentTime (RealMedia)

Usage

-- Lingo syntax
memberOrSpriteObjRef.currentTime

// JavaScript syntax
memberOrSpriteObjRef.currentTime;

Description

RealMedia sprite or cast member property; allows you to get or set the current time of the RealMedia stream, in milliseconds. If the RealMedia cast member is not playing, the value of this property is 0, which is the default setting. This is a playback property, and it is not saved.

If the stream is playing when the currentTime property is set or changed, a seek action takes place, the stream rebuffers, and then playback resumes at the new time. If the stream is paused (#paused mediaStatus value) when currentTime is set or changed, the stream redraws the frame at the new time, and it resumes playback if pausedAtStart is set to FALSE. When the stream is paused or stopped in the RealMedia viewer, mediaStatus is #paused. When the stream is stopped by the Lingo stop command, mediaStatus is #closed. This property has no effect if the stream's mediaStatus value is #closed. When you set integer values, they are clipped to the range from 0 to the duration of the stream.

Setting currentTime is equivalent to invoking the seek command: x.seek(n) is the same as x.currentTime = n. Changing currentTime or calling seek will require the stream to be rebuffed.

Example

The following examples show that the current time of the sprite 2 and the cast member Real is 15,534 milliseconds (15.534 seconds) from the beginning of the stream.

-- Lingo syntax
put(sprite(2).currentTime) -- 15534
put(member("Real").currentTime) -- 15534

// JavaScript syntax
put(sprite(2).currentTime) // 15534
put(member("Real").currentTime) // 15534

The following examples cause playback to jump 20,000 milliseconds (20 seconds) into the stream of sprite 2 and the cast member Real.
-- Lingo syntax
sprite(2).currentTime = 20000
member("Real").currentTime = 20000

// JavaScript syntax
sprite(2).currentTime = 20000
member("Real").currentTime = 20000

See also
duration (RealMedia, SWA), seek(), mediaStatus (RealMedia, Windows Media)

currentTime (Sprite)

Usage
 -- Lingo syntax
spriteObjRef.currentTime

// JavaScript syntax
spriteObjRef.currentTime;

Description
Sprite and sound channel property; returns the current playing time, in milliseconds, for a sound
sprite, QuickTime digital video sprite, or any Xtra extension that supports cue points. For a
sound channel, returns the current playing time of the sound member currently playing in the
given sound channel.

This property can be tested, but can only be set for traditional sound cast members (WAV, AIFF,
SND). When this property is set, the range of allowable values is from zero to the duration of
the member.

Shockwave Audio (SWA) sounds can appear as sprites in sprite channels, but they play sound in a
sound channel. You should refer to SWA sound sprites by their sprite channel number rather than
by a sound channel number.

Example
This statement displays the current time, in seconds, of the sound sprite in sprite channel 10.

-- Lingo syntax
member("time").text = string(sprite(10).currentTime/ 1000)

// JavaScript syntax
member("time").text = (sprite(10).currentTime / 1000).toString();

This statement causes the sound playing in sound channel 2 to skip to the point 2.7 seconds from
the beginning of the sound cast member:

-- Lingo syntax
sound(2).currentTime = 2700

// JavaScript syntax
sound(2).currentTime = 2700;

See also
duration (Member)
cursor

Usage

-- Lingo syntax
spriteObjRef.cursor

// JavaScript syntax
spriteObjRef.cursor;

Description

Sprite property; determines the cursor used when the pointer is over a sprite. Read/write.

This property stays in effect until you turn it off by setting the cursor to 0. Use the cursor property to change the cursor when the mouse pointer is over specific regions of the screen and to indicate regions where certain actions are possible when the user clicks on them.

When you set the cursor property in a given frame, Director keeps track of the sprite rectangle to determine whether to alter the cursor. This rectangle persists when the movie enters another frame unless you set the cursor property for that channel to 0.

- Use the following syntax to specify the number of a cast member to use as a cursor and its optional mask.

  -- Lingo syntax
  spriteObjRef.cursor = [castMemberObjRef, maskCastMemberObjRef]

  // JavaScript syntax
  spriteObjRef.cursor = [castMemberObjRef, maskCastMemberObjRef];

- Use the following syntax to specify default system cursors.

  -- Lingo syntax
  spriteObjRef.cursor = castMemberObjRef

  // JavaScript syntax
  spriteObjRef.cursor = castMemberObjRef;

The cursor property can be set to one of the following integer values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1, 0</td>
<td>Arrow</td>
</tr>
<tr>

</tbody>
</table>
To use custom cursors, set the `cursor` property to a list containing the cast member to be used as a cursor or to the number that specifies a system cursor. In Windows, a cursor must be a cast member, not a resource; if a cursor is not available because it is a resource, Director displays the standard arrow cursor instead. For best results, don't use custom cursors when creating cross-platform movies.

Custom cursor cast members must be no larger than 16 by 16 pixels, and must be 1-bit in depth. If the sprite is a bitmap that has matte ink applied, the cursor changes only when the cursor is over the matte portion of the sprite.

When the cursor is over the location of a sprite that has been removed, rollover still occurs. Avoid this problem by not performing rollovers at these locations or by relocating the sprite up above the menu bar before deleting it.

On the Macintosh, you can use a numbered cursor resource in the current open movie file as the cursor by setting `cursor` to the number of the cursor resource.

**Example**

This statement changes the cursor that appears over sprite 20 to a watch (Macintosh) or hourglass (Windows) cursor.

```lingo
-- Lingo syntax
sprite(20).cursor = 4
```

```javascript
// JavaScript syntax
sprite(20).cursor = 4;
```

**See also**

*Sprite*
**cursorSize**

**Usage**

-- Lingo syntax
memberObjRef.cursorSize

// JavaScript syntax
memberObjRef.cursorSize;

**Description**

Cursor cast member property; specifies the size of the animated color cursor cast member whichCursorCastMember.

<table>
<thead>
<tr>
<th>Specify size</th>
<th>For cursors up to:</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>16 by 16 pixels</td>
</tr>
<tr>
<td>32</td>
<td>32 by 32 pixels</td>
</tr>
</tbody>
</table>

Bitmap cast members smaller than the specified size are displayed at full size, and larger ones are scaled proportionally to the specified size.

The default value is 32 for Windows and 16 for the Macintosh. If you set an invalid value, an error message appears when the movie runs (but not when you compile).

This property can be tested and set.

**Example**

This command resizes the animated color cursor stored in cast member 20 to 32 by 32 pixels.

-- Lingo syntax
member(20).cursorSize = 32

// JavaScript syntax
member(20).cursorSize = 32;

**curve**

**Usage**

-- Lingo syntax
memberObjRef.curve[curveListIndex]

// JavaScript syntax
memberObjRef.curve[curveListIndex];

**Description**

This property contains the vertexList of an individual curve (shape) from a vector shape cast member. You can use the curve property along with the vertex property to get individual vertices of a specific curve in a vector shape.

A vertexList is a list of vertices, and each vertex is a property list containing up to three properties: a #vertex property with the location of the vertex, a #handle1 property with the location of the first control point for that vertex, and a #handle2 property with the location of the second control point for that vertex. See vertexList.
Example

This statement displays a sample list of vertices of the third curve of vector shape member SimpleCurves:

-- Lingo syntax
put(member("SimpleCurves").curve[3])
  -- [[#vertex: point(113.0000, 40.0000), #handle1: point(32.0000, 10.0000), #handle2: point(-32.0000, -10.0000)], [#vertex: point(164.0000, 56.0000)]]

// JavaScript syntax
put(member("SimpleCurves").curve[3]);
  // [[#vertex: point(113.0000, 40.0000), #handle1: point(32.0000, 10.0000), #handle2: point(-32.0000, -10.0000)], [#vertex: point(164.0000, 56.0000)]]

This statement moves the first vertex of the first curve in a vector shape down and to the right by 10 pixels:

-- Lingo syntax

// JavaScript syntax
member(1).curve[1].vertex[1] = member(1).curve[1].vertex[1] + point(10, 10);

The following code moves a sprite to the location of the first vertex of the first curve in a vector shape. The vector shape’s originMode must be set to #topLeft for this to work.

-- Lingo syntax
vertexLoc = member(1).curve[1].vertex[1]
spriteLoc = mapMemberToStage(sprite(3), vertexLoc)
sprite(7).loc = spriteLoc

// JavaScript syntax
var vertexLoc = member(1).curve[1].vertex[1];
var spriteLoc = mapMemberToStage(sprite(3), vertexLoc);
sprite(7).loc = spriteLoc;

debuge

Usage

member(whichCastmember).model(whichModel).debug

Description

3D model property; indicates whether the bounding sphere and local axes of the model are displayed.

Example

This statement sets the debug property of the model Dog to TRUE.
member("ParkScene").model("Dog").debug = TRUE

See also

boundingSphere
**debugPlaybackEnabled**

**Usage**

-- Lingo syntax
_player.debugPlaybackEnabled

// JavaScript syntax
_player.debugPlaybackEnabled;

**Description**

Player property; in Windows, opens a Message window for debugging purposes in Shockwave and projectors. On the Macintosh, a log file is generated to allow `put` statements to output data for debugging purposes. Read/write.

In Windows, this property does not have any effect when used in the Director application. Once the Message window is closed, it cannot be reopened for a particular Shockwave Player or projector session. If more than one movie with Shockwave content uses this script in a single browser, only the first will open a Message window, and the Message window will be tied to the first movie alone.

On the Macintosh, the generated log file is located in the Shockwave Player folder at HardDrive/ System Folder/Extensions/Macromedia/Shockwave.

To open this Message window, set the `debugPlaybackEnabled` property to `TRUE`. To close the window, set the `debugPlaybackEnabled` property to `FALSE`.

**Example**

This statement opens the Message window in either Shockwave Player or a projector:

-- Lingo syntax
_player.debugPlaybackEnabled = TRUE

// JavaScript syntax
_player.debugPlaybackEnabled = true;

**See also**

`Player`, `put()`

**decayMode**

**Usage**

member(\$whichCastmember).camera(\$whichCamera).fog.decayMode
sprite(\$whichSprite).camera(index).fog.decayMode

**Description**

3D property; indicates the manner in which fog density builds from minimum to maximum density when the camera's `fog.enabled` property is set to `TRUE`.

The following are the possible values for this property:

- `#linear`: the fog density is linearly interpolated between `fog.near` and `fog.far`.
- `#exponential`: `fog.far` is the saturation point; `fog.near` is ignored.
- `#exponential2`: `fog.near` is the saturation point; `fog.far` is ignored.

The default setting for this property is `#exponential`.
Example

This statement sets the `decayMode` property of the fog of the camera Defaultview to `#linear`. If the fog's `enabled` property is set to `TRUE`, the density of the fog will steadily increase between the distances set by the fog's `near` and `far` properties. If the `near` property is set to 100 and the `far` property is set to 1000, the fog will begin 100 world units in front of the camera and gradually increase in density to a distance of 1000 world units in front of the camera.

```lingo
member("3d world").camera("Defaultview").fog.decayMode = #linear
```

See also

`fog`, `near (fog)`, `far (fog)`, `enabled (fog)`

defaultRect

Usage

-- Lingo syntax
```lingo
memberObjRef.defaultRect
```

// JavaScript syntax
```javascript
memberObjRef.defaultRect;
```

Description

Cast member property; controls the default size used for all new sprites created from a Flash movie or vector shape cast member. The `defaultRect` setting also applies to all existing sprites that have not been stretched on the Stage. You specify the property values as a Director rectangle; for example, `rect(0,0,32,32)`.

The `defaultRect` member property is affected by the cast member's `defaultRectMode` member property. The `defaultRectMode` property is always set to `#Flash` when a movie is inserted into a cast, which means the original `defaultRect` setting is always the size of the movie as it was originally created in Flash. Setting `defaultRect` after that implicitly changes the cast member's `defaultRectMode` property to `#fixed`.

This property can be tested and set.

Example

This handler accepts a cast reference and a rectangle as parameters. It then searches the specified cast for Flash cast members and sets their `defaultRect` property to the specified rectangle.

```lingo
on setDefaultFlashRect(whichCast, whichRect)
    repeat with i = 1 to castLib(whichCast).member.count
        if member(i, whichCast).type = #flash then
            member(i, whichCast).defaultRect = whichRect
        end if
    end repeat
end
```
function setDefaultFlashRect(whichCast, whichRect) {
    var i = 1;
    while( i < (castLib(whichCast).member.count) + 1)
        var tp = member(i, whichCast).type;
        if (tp = "flash") {
            member(i, whichCast).defaultRect = whichRect;
            i++;
        }
}

See also
  defaultRectMode, flashRect

defaultRectMode

Usage
  -- Lingo syntax
  memberObjRef.defaultRectMode

  // JavaScript syntax
  memberObjRef.defaultRectMode;

Description
Cast member property; controls how the default size is set for all new sprites created from Flash
movie or vector shape cast members. You specify the property value as a Director rectangle; for
example, rect(0,0,32,32).
The defaultRectMode property does not set the actual size of a Flash movie’s default rectangle; it
only determines how the default rectangle is set. The defaultRectMode member property can
have these values:
  • \#flash (default)—Sets the default rectangle using the size of the movie as it was originally
    created in Flash.
  • \#fixed—Sets the default rectangle using the fixed size specified by the defaultRect
    member property.
The defaultRect member property is affected by the cast member’s defaultRectMode member
property. The defaultRectMode property is always set to \#flash when a movie is inserted into a
cast, which means the original defaultRect setting is always the size of the movie as it was
originally created in Flash. Setting defaultRect after that implicitly changes the cast member’s
defaultRectMode property to \#fixed.
This property can be tested and set.

Example
This handler accepts a cast reference and a rectangle as parameters. It then searches the specified
cast for Flash cast members, sets their defaultRectMode property to \#fixed, and then sets their
defaultRect property to rect(0,0,320,240).
-- Lingo syntax
on setDefaultRectSize(whichCast)
    repeat with i = 1 to castLib(whichCast).member.count
        if member(i, whichCast).type = #flash then
            member(i, whichCast).defaultRectMode = #fixed
            member(i, whichCast).defaultRect = rect(0,0,320,240)
        end if
    end repeat
end

// JavaScript syntax
function setDefaultRectSize(whichCast) {
    var i = 1;
    while( i < (castLib(whichCast).member.count) + 1)
        var tp = member(i, whichCast).type;
        if (tp = "flash") {
            member(i, whichCast).defaultRectMode = symbol("fixed");
            member(i, whichCast).defaultRect = rect(0,0,320,240);
            i++
        }
    }
}

See also
flashRect, defaultRect

density

Usage

member(whichCast).member(whichShader).density
member(whichCast).model(whichModel).shader.density
member(whichCast).model(whichModel).shaderList[index].density

Description

3D #engraver and #newsprint shader property; adjusts the number of lines or dots used to create the effects of these specialized shader types. Higher values result in more lines or dots.

For #engraver shaders, this property adjusts the number of lines used to create the image. The range is 0 to 100 and the default value is 40.

For #newsprint shaders, this property adjusts the number of dots used to create the image. The value can be from 0 to 100 and the default value is 45.

Example

The following statement sets the density property of the shader named EngShader to 10. The lines used by this #engraver shader to create its stylized image will be coarse and far apart.

member("scene").shader("EngShader").density = 10

The following statement sets the density property of the shader gbShader to 100. The dots used by this #newsprint shader to create its stylized image will be very fine and close together.

member("scene").shader("gbShader").density = 100

See also
newShader
**depth (3D)**

**Usage**

\[
\text{member}(\text{whichCastMember}).\text{model}(\text{whichModel}).\text{sds.depth}
\]

**Description**

3D subdivision surfaces (sds) modifier property; specifies the maximum number of levels of resolution that the model can display when using the sds modifier.

If the sds modifier’s error and tension settings are low, increasing the depth property will have a more pronounced effect on the model's geometry.

The sds modifier cannot be used with the ink or toon modifiers, and you should be careful when using the sds modifier with the lod modifier.

**Example**

This statement sets the depth property of the sds modifier for the model named Baby to 3. If the sds modifier’s error and tension settings are low, this will cause a very pronounced effect on Baby's geometry.

\[
\text{member}('\text{Scene}').\text{model}('\text{Baby}').\text{sds.depth} = 3
\]

**See also**

sds (modifier). error. tension

---

**depth (Bitmap)**

**Usage**

\[
\text{ImageObject.depth}
\]

\[
\text{member}(\text{whichCastMember}).\text{depth}
\]

\[
\text{the depth of member whichCastMember}
\]

**Description**

Image object or bitmap cast member property; displays the color depth of the given image object or bitmap cast member.

<table>
<thead>
<tr>
<th>Depth</th>
<th>Number of Colors</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Black and white</td>
</tr>
<tr>
<td>2</td>
<td>4 colors</td>
</tr>
<tr>
<td>4, 8</td>
<td>16 or 256 palette-based colors, or gray levels</td>
</tr>
<tr>
<td>16</td>
<td>Thousands of colors</td>
</tr>
<tr>
<td>32</td>
<td>Millions of colors</td>
</tr>
</tbody>
</table>

This property can be tested but not set.

**Example**

This statement displays the color depth of the image object stored in the variable newImage. The output appears in the Message window.

--- Lingo syntax

\[
\text{put}(\text{newImage.depth})
\]
// JavaScript syntax
trace(newImage.depth);

This statement displays the color depth of the cast member Shrine in the Message window:

-- Lingo syntax
put(member("Shrine").depth)

-- JavaScript syntax
put(member("Shrine").depth);

depthBufferDepth

Usage
getRendererServices().depthBufferDepth

Description
3D rendererServices property; indicates the precision of the hardware depth buffer of the user's system. The value is either 16 or 24, depending on the user's hardware settings.

Example

This statement shows that the depthBufferDepth value of the user's video card is 16:

put getRendererServices().depthBufferDepth
-- 16

See also
getRendererServices(), getHardwareInfo(), colorBufferDepth
deskTopRectList

Usage

-- Lingo syntax
_system.deskTopRectList

// JavaScript syntax
_system.deskTopRectList;

Description

System property; displays the size and position on the desktop of the monitors connected to a computer. Read-only.

This property is useful for checking whether objects such as windows, sprites, and pop-up windows appear entirely on one screen.

The result is a list of rectangles, where each rectangle is the boundary of a monitor. The coordinates for each monitor are relative to the upper left corner of monitor 1, which has the value (0,0). The first set of rectangle coordinates is the size of the first monitor. If a second monitor is present, a second set of coordinates shows where the corners of the second monitor are relative to the first monitor.
Example

This statement tests the size of the monitors connected to the computer and displays the result in the Message window:

```-- Lingo syntax
put(_system.deskTopRectList)
```

```// JavaScript syntax
put(_system.deskTopRectList);
```

This handler tells how many monitors are in the current system:

```-- Lingo syntax
on countMonitors
    return _system.deskTopRectList
end
```

```// JavaScript syntax
function countMonitors() {
    return _system.deskTopRectList;
}
```

See also

System

diffuse

Usage

```member(whichCastmember).shader(whichShader).diffuse
member(whichCastmember).model(whichModel).shader.diffuse
member(whichCastmember).model(whichModel).shaderList[[index]].\diffuse```

Description

3D `#standard` shader property; indicates a color that is blended with the first texture of the shader when the following conditions are met:

- the shader's `useDiffuseWithTexture` property is set to `TRUE`, and either
- the `blendFunction` property of the shader is set to `#add` or `#multiply`, or
- the `blendFunction` property of the shader is set to `#blend`, the `blendSource` property of the shader is set to `#constant`, and the value of the `blendConstant` property of the shader is less than 100.

The default value is of this property is `rgb(255, 255, 255)`.

Example

This statement sets the `diffuse` property of the shader named Globe to `rgb(255, 0, 0)`.

```
member("MysteryWorld").shader("Globe").diffuse = rgb(255, 0, 0)
```

See also

`diffuseColor`, `useDiffuseWithTexture`, `blendFunction`, `blendSource`, `blendConstant`
**diffuseColor**

**Usage**

member(whichCastmember).diffuseColor

**Description**

3D cast member property; indicates a color that is blended with the first texture of the first shader of the cast member when the following conditions are met:

- the shader’s useDiffuseWithTexture property is set to TRUE, and either
- the blendFunction property of the shader is set to #add or #multiply, or
- the blendFunction property of the shader is set to #blend, the blendSource property of the shader is set to #constant, and the value of the blendConstant property of the shader is less than 100.

The default value is of the diffuseColor property is rgb(255, 255, 255).

**Example**

This statement sets the diffuseColor property of the cast member named Room to rgb(255, 0, 0).

member("Room").diffuseColor = rgb(255, 0, 0)

**See also**

diffuse, useDiffuseWithTexture, blendFunction, blendSource, blendConstant

**diffuseLightMap**

**Usage**

- member(whichCastmember).shader(whichShader).diffuseLightMap
- member(whichCastmember).model(whichModel).shader.diffuseLightMap
- member(whichCastmember).model(whichModel).shaderList[index].diffuseLightMap

**Description**

3D #standard shader property; specifies the texture to use for diffuse light mapping.

When you set this property, the following properties are automatically set:

- The second texture layer of the shader is set to the texture you specified.
- The value of textureModeList[2] is set to #diffuse.
- The value of blendFunctionList[2] is set to #multiply.
- The value of blendFunctionList[1] is set to #replace.

**Example**

This statement sets the texture named Oval as the diffuseLightMap property of the shader used by the model named GlassBox.

member("3DPlanet").model("GlassBox").shader.diffuseLightMap = \
member("3DPlanet").texture("Oval")

**See also**

blendFunctionList, textureModeList, glossMap, region, specularLightMap
**digitalVideoTimeScale**

**Usage**

```
-- Lingo syntax
_player.digitalVideoTimeScale

// JavaScript syntax
_player.digitalVideoTimeScale;
```

**Description**

Player property; determines the time scale, in units per second, that the system uses to track digital video cast members. Read/write.

The `digitalVideoTimeScale` property can be set to any value you choose. The value of this property determines the fraction of a second that is used to track the video, as in the following examples:

- **100**—The time scale is 1/100 of a second (and the movie is tracked in 100 units per second).
- **500**—The time scale is 1/500 of a second (and the movie is tracked in 500 units per second).
- **0**—Director uses the time scale of the movie that is currently playing.

Set `digitalVideoTimeScale` to precisely access tracks by ensuring that the system’s time unit for video is a multiple of the digital video’s time unit. Set the `digitalVideoTimeScale` property to a higher value to enable finer control of video playback.

**Example**

This statement sets the time scale that the system uses to measure digital video to 600 units per second:

```
-- Lingo syntax
_player.digitalVideoTimeScale = 600

// JavaScript syntax
_player.digitalVideoTimeScale = 600;
```

**See also**

`Player`

---

**digitalVideoType**

**Usage**

```
member(whichCastMember).digitalVideoType
```

the digitalVideoType of member `whichCastMember`

**Description**

Cast member property; indicates the format of the specified digital video. Possible values are `#quickTime` or `#videoForWindows`.

This property can be tested but not set.
Example

The following statement tests whether the cast member Today's Events is a QuickTime or AVI (Audio-Video Interleaved) digital video and displays the result in the Message window:

```
put member("Today's Events").digitalVideoType
```

See also

`quickTimeVersion()`

direction

Usage

```
member(whichCastmember).modelResource(whichModelResource).emitter.direction
```

Description

3D emitter property; a vector that indicates the direction in which the particles of a particle system are emitted. A particle system is a model resource whose type is #particle.

The primary direction of particle emission is the vector set by the emitter's `direction` property. However, the direction of emission of a given particle will deviate from that vector by a random angle between 0 and the value of the emitter's `angle (3D)` property.

Setting `direction` to `vector(0,0,0)` causes the particles to be emitted in all directions.

The default value of this property is `vector(1,0,0)`.

Example

In this example, ThermoSystem is a model resource whose type is #particle. This statement sets the `direction` property of ThermoSystem's emitter to `vector(1, 0, 0)`, which causes the particles of ThermoSystem to be emitted into a conical region whose axis is the X axis of the 3D world.

```
member("Fires").modelResource("ThermoSystem").emitter.
direction = vector(1,0,0)
```

See also

`emitter`, `angle (3D)`

directionalColor

Usage

```
member(whichCastmember).directionalColor
```

Description

3D cast member property; indicates the RGB color of the default directional light of the cast member.

The default value of this property is rgb(255, 255, 255).
Example

This statement sets the directionalColor property of the cast member named Room to rgb(0, 255, 0). The default directional light of the cast member will be green. This property can also be set in the Property inspector.

```
member("Room").directionalcolor = rgb(0, 255, 0)
```

See also

directionalPreset

directionalPreset

Usage

```
member(whichCastmember).directionalPreset
```

Description

3D cast member property; indicates the direction from which the default directional light shines, relative to the camera of the sprite.

Changing the value of this property results in changes to the position and rotation properties of the light’s transform.

Possible values of directionalPreset include the following:

- #topLeft
- #topCenter
- #topRight
- #middleLeft
- #middleCenter
- #middleRight
- #bottomLeft
- #bottomCenter
- #bottomRight
- #None

The default value of this property is #topCenter.

Example

This statement sets the directionalPreset property of the cast member named Room to #middleCenter. This points the default light of Room so it will shine on the middle center the current view of the camera of the sprite. This property can also be set in the Property inspector.

```
member("Room").directionalpreset = #middleCenter
```

See also

directionalColor
**directToStage**

**Usage**

-- Lingo syntax

memberOrSpriteObjRef.directToStage

// JavaScript syntax

memberOrSpriteObjRef.directToStage;

**Description**

Cast member and sprite property; determines the layer where a digital video, animated GIF, vector shape, 3D, Windows Media, or Flash Asset cast member plays.

If this property is TRUE (1), the cast member plays in front of all other layers on the Stage, and ink effects have no effect.

If this property is FALSE (0), the cast member can appear in any layer of the Stage's animation planes, and ink effects affect the appearance of the sprite.

- Use the syntax `member(whichCastMember).directToStage` for digital video or animated GIFs.
- Use the syntax `sprite(whichSprite).directToStage` for Flash or vector shapes.
- Use either syntax for 3D cast members or sprites.

Using this property improves the playback performance of the cast member or sprite.

No other cast member can appear in front of a `directToStage` sprite. Also, ink effects do not affect the appearance of a `directToStage` sprite.

When a sprite's `directToStage` property is TRUE, Director draws the sprite directly to the screen without first compositing it in the Director offscreen buffer. The result can be similar to the trails ink effect of the Stage.

Explicitly refresh a trailed area by turning the `directToStage` property off and on, using a full-screen transition, or “wiping” another sprite across this area. (In Windows, if you don’t do this, you can branch to another similar screen, and the video may not completely disappear.)

To see an example of `directToStage` used in a completed movie, see the QT and Flash movie in the Learning/Lingo Examples folder inside the Director application folder.

**Example**

This statement makes the QuickTime movie The Residents always play in the top layer of the Stage:

-- Lingo syntax

member("The Residents").directToStage = 1

// JavaScript syntax

member("The Residents").directToStage = 1;
disableImagingTransformation

Usage

-- Lingo syntax
_player.disableImagingTransformation

// JavaScript syntax
_player.disableImagingTransformation;

Description
Player property; determines whether Director automatically takes Stage scrolling or zooming into account capturing the image of the Stage. Read/write.

When TRUE, this property prevents Director from automatically taking Stage scrolling or zooming into account when the image property is used to get the image of the Stage. Zooming and scrolling of the Stage will affect the appearance of the image captured by using image.

When FALSE, Director will always capture the image of the Stage as if the Stage window was zoomed at 100% and was not scrolled out from the center of the Stage window. FALSE is the default value.

Example

This statement sets disableImagingTransformation to TRUE:

-- Lingo syntax
_player.disableImagingTransformation = TRUE

// JavaScript syntax
_player.digitalVideoTimeScale = true;

See also

image (Image), Player

displayFace

Usage

member(whichTextCastmember).displayFace
member(which3DCastmember).modelResource(whichModelResource).displayFace

Description
3D text property; a linear list indicating which face or faces of the 3D text to display. Possible values include #front, #tunnel, and #back. You can show any combination of faces, and the list can be in any order.

The default value of this property is [#front, #back, #tunnel].

For text cast members, this is a member property. For extruded text in a 3D cast member, this is a model resource property.

Example

In this example, the cast member named Rugsign is a text cast member. This statement sets the displayFace property of Rugsign to [#tunnel]. When Rugsign is displayed in 3D mode, its front and back faces will not appear.

member("Rugsign").displayFace = [#tunnel]
In this example, the model resource of the model named Slogan is extruded text. This statement sets the displayFace property of Slogan’s model resource to [#back, #tunnel]. The front face of Slogan will not be drawn.

    member("scene").model("Slogan").resource.displayFace = [#back, #tunnel]

See also

extrude3D, displayMode

displayMode

Usage

    member(whichTextCastmember).displayMode

Description

Text cast member property; specifies whether the text will be rendered as 2D text or 3D text.

If this property is set to #Mode3D, the text is shown in 3D. You can set the 3D properties (such as displayFace and bevelDepth) of the text, as well as the usual text properties (such as text and font). The sprite containing this cast member becomes a 3D sprite.

If this property is set to #ModeNormal, the text is shown in 2D. The default value of this property is #ModeNormal.

Example

    In this example, the cast member named Logo is a text cast member. This statement causes Logo to be displayed in 3D.

        member("Logo").displayMode = #mode3D

See also

extrude3D

displayRealLogo

Usage

    -- Lingo syntax
    memberOrSpriteObjRef.displayRealLogo

    // JavaScript syntax
    memberOrSpriteObjRef.displayRealLogo;

Description

RealMedia sprite or cast member property; allows you to set or get whether the RealNetworks logo is displayed (TRUE) or not (FALSE). When set to TRUE, this property displays the RealNetworks logo in the RealMedia viewer at the beginning of the stream, when the video is stopped, or when the video is rewound.

The default value of this property is TRUE (1). Integer values other than 1 or 0 are treated as TRUE.
Example

The following examples show that the `displayRealLogo` property for sprite 2 and the cast member `Real` is set to `TRUE`, which means that the RealNetworks logo is displayed when the movie starts to play and when it is stopped or rewound.

```-- Lingo syntax
put(sprite(2).displayRealLogo) -- 1
put(member("Real").displayRealLogo) -- 1
// JavaScript syntax
trace(sprite(2).displayRealLogo); // 1
put(member("Real").displayRealLogo); // 1```

The following examples set the `displayRealLogo` property for sprite 2 and the cast member `Real` to `FALSE`, which means that the RealNetworks logo is not displayed.

```-- Lingo syntax
sprite(2).displayRealLogo = FALSE
member("Real").displayRealLogo = FALSE
// JavaScript syntax
sprite(2).displayRealLogo = 0;
member("Real").displayRealLogo = 0;```

displayTemplate

Usage

```-- Lingo syntax
_movie.displayTemplate
// JavaScript syntax
_movie.displayTemplate;```

Description

Movie property; provides access to a list of properties that are applied to the window in which a movie is playing back. Read/write.

The `displayTemplate` property provides access to the properties of the Window object that are used to specify default window settings. Therefore, `displayTemplate` is used on the Movie object to return or set default window settings in the same way the `appearanceOptions` and `titlebarOptions` properties are used on the Window object.

The `displayTemplate` property provides access to the following properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>appearanceOptions</code></td>
<td>A property list that stores appearance options for a window. The appearance options are <code>mask</code>, <code>border</code>, <code>metal</code>, <code>dragRegionMask</code>, <code>shadow</code>, and <code>liveresize</code>. For more information, see <code>appearanceOptions</code>.</td>
</tr>
<tr>
<td><code>dockingEnabled</code></td>
<td>Determines whether a movie in a window (MIAW) will be dockable when opened during authoring. If <code>TRUE</code>, the window can be docked. If <code>FALSE</code>, the window cannot be docked. The default value is <code>FALSE</code>. For more information, see <code>dockingEnabled</code>.</td>
</tr>
</tbody>
</table>
These statements display the `displayTemplate` properties and their corresponding values in the Message window.

```plaintext
-- Lingo syntax
trace(_movie.displayTemplate)

// JavaScript syntax
trace(_movie.displayTemplate);
```

These statements set various `displayTemplate` properties.

```plaintext
-- Lingo syntax
_movie.displayTemplate.dockingEnabled = TRUE
_movie.displayTemplate.resizable = FALSE
_movie.displayTemplate.appearanceOptions.mask = member("mask")
_movie.displayTemplate.titlebarOptions.sideTitlebar = TRUE

// JavaScript syntax
_movie.displayTemplate.dockingEnabled = true;
_movie.displayTemplate.resizable = false;
_movie.displayTemplate.appearanceOptions.mask = member("mask");
_movie.displayTemplate.titlebarOptions.sideTitlebar = true;
```

See also

- `appearanceOptions`
- `dockingEnabled`
- `Movie`
- `resizable`
- `systemTrayIcon`
- `title (Window)`
- `titlebarOptions`
- `type (Window)`
- `Window`
distribution

Usage

member(whichCastmember).modelResource(whichModelResource).emitter.distribution

Description

3D emitter property; indicates how the particles of a particle system are distributed across the emitter’s region at their creation. The possible values of this property are #gaussian or #linear. The default value is #linear.

Example

In this example, ThermoSystem is a model resource whose type is #particle. This statement sets the distribution property of ThermoSystem’s emitter to #linear, which causes the particles of ThermoSystem to be evenly distributed across their origin region at their birth.

member("Fires").modelResource("ThermoSystem").emitter.
distribution = #linear

See also

emitter, region

dither

Usage

-- Lingo syntax
memberObjRef.dither

// JavaScript syntax
memberObjRef.dither;

Description

Bitmap cast member property; dithers the cast member when it is displayed at a color depth of 8 bits or less (256 colors) if the display must show a color gradation not in the cast member (TRUE), or tells Director to choose the nearest color out of those available in the current palette (FALSE).

For both performance and quality reasons, you should set dither to TRUE only when higher display quality is necessary. Dithering is slower than remapping, and artifacts may be more apparent when animating over a dithered image.

If the color depth is greater than 8 bits, this property has no effect.

See also

depth (Bitmap)
dockingEnabled

Usage
--- Lingo syntax
_movie.displayTemplate.dockingEnabled
windowObjRef.dockingEnabled

// JavaScript syntax
_movie.displayTemplate.dockingEnabled;
windowObjRef.dockingEnabled;

Description
Movie and Window property; specifies whether a movie in a window (MIAW) will be a dockable window when opened during authoring. Read/write.

This property cannot be accessed directly from a Movie object; you access this property from the Movie object’s displayTemplate property.

The default value of this property is FALSE, which specifies that a MIAW will not be dockable when opened during authoring. If this property is set to TRUE, the value of the Window object’s type property determines how the window will appear during authoring.

- If dockingEnabled is TRUE and type is set to #document, the MIAW will look and act like a document windows in Director. The window will appear in the “view port” area and be dockable with the Stage, Score, and Cast windows, media editors, and message windows. However, the window will not be able to group with any of these windows.
- If dockingEnabled is TRUE and type is set to #tool, the MIAW will look and act like one of tool windows in Director. The window will be able to group with all tool windows except the Property inspector and the Tool palette.
- If dockingEnabled is TRUE and type is set to #dialog, the type is ignored and the window will be an authoring window.

This property is ignored in projectors.

Example
These statements set the dockingEnabled property to TRUE.

--- Lingo syntax
_movie.displayTemplate.dockingEnabled = TRUE -- from the Movie object
window("Instructions").dockingEnabled = TRUE -- from the Window object

// JavaScript syntax
_movie.displayTemplate.dockingEnabled = true; // from the Movie object
window("Instructions").dockingEnabled = true; // from the Window object

See also
appearanceOptions, displayTemplate, Movie, titlebarOptions, type (Window), Window
**domain**

**Usage**

-- Lingo syntax
dvdObjRef.domain

// JavaScript syntax
dvdObjRef.domain;

**Description**

DVD property; returns a symbol that indicates the current domain. Read-only.

**See also**

DVD

**doubleClick**

**Usage**

-- Lingo syntax
_mouse.doubleClick

// JavaScript syntax
_mouse.doubleClick;

**Description**

Mouse property; tests whether two mouse clicks within the time set for a double-click occurred as a double-click rather than two single clicks (TRUE), or if they didn't occur within the time set, treats them as single clicks (FALSE). Read-only.

**Example**

This statement branches the playhead to the frame Enter Bid when the user double-clicks the mouse button:

--- Lingo syntax
if (_mouse.doubleClick) then
   _movie.go("Enter Bid")
end if

// JavaScript syntax
if (_mouse.doubleClick) {
   _movie.go("Enter Bid");
}

**See also**

clickLoc, clickOn, Mouse
drag

Usage
member(whichCastmember).modelResource(whichModelResource).drag

Description
3D #particle model resource property; indicates the percentage of each particle’s velocity that is lost in each simulation step. This property has a range of 0 (no velocity lost) to 100 (all velocity lost and the particle stops moving). The default value is 0.

Example
In this example, ThermoSystem is a model resource whose type is #particle. This statement sets the drag property of ThermoSystem to 5, applying a large resistance to the motion of the particles of ThermoSystem and preventing them from traveling very far.
member("Fires").modelResource("ThermoSystem").drag = 5

See also
wind, gravity

drawRect

Usage
-- Lingo syntax
windowObjRef.drawRect

// JavaScript syntax
windowObjRef.drawRect;

Description
Window property; identifies the rectangular coordinates of the Stage of the movie that appears in a window. Read/write.

The coordinates are given as a rectangle, with entries in the order left, top, right, and bottom.

This property is useful for scaling or panning movies, but it does not rescale text and field cast members. Scaling bitmaps can affect performance.

Example
This statement displays the current coordinates of the movie window called Control Panel:
-- Lingo syntax
put(window("Control Panel").drawRect)

// JavaScript syntax
put(window("Control Panel").drawRect);

The following statement sets the rectangle of the movie to the values of the rectangle named movieRectangle. The part of the movie within the rectangle is what appears in the window.
-- Lingo syntax
movieRectangle = rect(10, 20, 200, 300)
window("Control Panel").drawRect = movieRectangle
// JavaScript syntax
var movieRectangle = rect(10, 20, 200, 300);
window("Control Panel").drawRect = movieRectangle;

The following lines cause the Stage to fill the main monitor area:
-- Lingo syntax
_movie.stage.drawRect = _system.deskTopRectList[1]
_movie.stage.rect = _system.deskTopRectList[1]

// JavaScript syntax
_movie.stage.drawRect = _system.deskTopRectList[1];
_movie.stage.rect = _system.deskTopRectList[1];

See also
rect(), Window

dropShadow

Usage
-- Lingo syntax
memberObjRef.dropShadow

// JavaScript syntax
memberObjRef.dropShadow;

Description
Cast member property; determines the size of the drop shadow in pixels, for text in a field cast member.

Example
This statement sets the drop shadow of the field cast member Comment to 5 pixels:
-- Lingo syntax
member("Comment").dropShadow = 5

// JavaScript syntax
member("Comment").dropShadow = 5;

duration (3D)

Usage
member(whichCastmember).motion(whichMotion).duration
motionObjectReference.duration

Description
3D property; lets you get the time in milliseconds that it takes the motion specified in the whichMotion parameter to play to completion. This property is always greater than or equal to 0.

Example
This statement shows the length in milliseconds of the motion Kick.
put member("GbMember").motion("Kick").duration
-- 5100.0000

See also
motion, currentTime (3D), play() (3D), queue() (3D)
duration (DVD)

Usage

-- Lingo syntax
dvdObjRef.duration

// JavaScript syntax
dvdObjRef.duration;

Description

DVD property; returns the total title time, in milliseconds. Read-only.

See also

DVD

duration (Member)

Usage

-- Lingo syntax
memberObjRef.duration

// JavaScript syntax
memberObjRef.duration;

Description

Cast member property; determines the duration of the specified Shockwave Audio (SWA),
transition, Windows Media, and QuickTime cast members.

• When whichCastMember is a streaming sound file, this property indicates the duration of the
  sound. The duration property returns 0 until streaming begins. Setting preloadTime to 1
  second allows the bit rate to return the actual duration.

• When whichCastMember is a digital video cast member, this property indicates the digital
  video's duration. The value is in ticks.

• When whichCastMember is a transition cast member, this property indicates the transition's
  duration. The value for the transition is in milliseconds. During playback, this setting has the
  same effect as the Duration setting in the Frame Transition dialog box.

This property can be tested for all cast members that support it, but only set for transitions.

To see an example of duration used in a completed movie, see the QT and Flash movie in the
Learning/Lingo Examples folder inside the Director application folder.

Example

If the SWA cast member Louie Prima has been preloaded, this statement displays the sound’s
duration in the field cast member Duration Displayer:

-- Lingo syntax
on exitFrame
  if member("Louie Prima").state = 2 then
    member("Duration Displayer").text = \
      string(member("Louie Prima").duration)
  end if
end
// JavaScript syntax
function exitFrame() {
  if (member("Louie Prima").state == 2) {
    member("Duration Displayer").text = member("Louie Prima").duration.toString();
  }
}

duration (RealMedia, SWA)

Usage

-- Lingo syntax
memberOrSpriteObjRef.duration

// JavaScript syntax
memberOrSpriteObjRef.duration;

Description

RealMedia or Shockwave audio sprite or cast member property; returns the duration of a RealMedia or Shockwave Audio stream, in milliseconds. The duration of the stream is not known until the cast member starts to play. If the stream is from a live feed or has not been played, the value of this property is 0. This property can be tested but not set.

Example

The following examples show that the duration of the RealMedia stream in sprite 2 and the cast member Real is 100,500 milliseconds (100.500 seconds).

-- Lingo syntax
put(sprite(2).duration) -- 100500
put(member("Real").duration) -- 100500

// JavaScript syntax
put(sprite(2).duration); // 100500
put(member("Real").duration); // 100500

See also

play() (RealMedia, SWA, Windows Media), seek(), currentTime (RealMedia)

editable

Usage

-- Lingo syntax
spriteObjRef.editable

// JavaScript syntax
spriteObjRef.editable;

Description

Sprite property; determines whether a specified sprite can be edited on the Stage (TRUE) or not (FALSE). Read/write.

When the cast member property is set, the setting is applied to all sprites that contain the field. When this property is set, only the specified sprite is affected.
You can also make a field sprite editable by using the Editable option in the Field Cast Member Properties dialog box.

You can make a field sprite editable by using the Editable option in the Score.

For the value set by a script to last beyond the current sprite, the sprite must be a scripted sprite.

**Example**

This handler first makes the sprite channel a puppet and then makes the field sprite editable:

```-- Lingo syntax
on myNotes
_movie.puppetSprite(5, TRUE)
sprite(5).editable = TRUE
end
// JavaScript syntax
function myNotes() {
_movie.puppetSprite(5, true);
sprite(5).editable = true;
}
```

This statement checks whether a field sprite is editable and displays a message if it is:

```-- Lingo syntax
if (sprite(13).editable = TRUE) then
    member("Notice").text = "Please enter your answer below."
end if
// JavaScript syntax
if (sprite(13).editable == true) {
    member("Notice").text = "Please enter your answer below."
}
```

**See also**

Sprite

**editShortCutsEnabled**

**Usage**

```-- Lingo syntax
_movie.editShortCutsEnabled
// JavaScript syntax
_movie.editShortCutsEnabled;
```

**Description**

Movie property; determines whether cut, copy, and paste operations and their keyboard shortcuts function in the current movie. Read/write.

When set to `TRUE`, these text operations function. When set to `FALSE`, these operations are not allowed. The default is `TRUE` for movies made in Director 8 and later, `FALSE` for movies made in versions of Director prior to Director 8.
Example

This statement disables cut, copy, and paste operations:

-- Lingo syntax
_movie.editShortCutsEnabled = 0

// JavaScript syntax
_movie.editShortCutsEnabled = 0;

See also

Movie

elapsedTime

Usage

-- Lingo syntax
.soundChannelObjRef.elapsedTime

// JavaScript syntax
.soundChannelObjRef.elapsedTime;

Description

Sound Channel property; gives the time, in milliseconds, that the current sound member in a sound channel has been playing. Read-only.

The elapsed time starts at 0 when the sound begins playing and increases as the sound plays, regardless of any looping, setting of the currentTime or other manipulation. Use the currentTime to test for the current absolute time within the sound.

The value of this property is a floating-point number, allowing for measurement of sound playback to fractional milliseconds.

Example

This idle handler displays the elapsed time for sound channel 4 in a field on the Stage during idles:

-- Lingo syntax
on idle
  member("time").text = string(sound(4).elapsedTime)
end idle

// JavaScript syntax
function idle() {
  member("time").text = sound(4).elapsedTime.toString();
}

See also

currentTime (Sprite), Sound Channel
emissive

Usage

member(whichCastmember).shader(whichShader).emissive
member(whichCastmember).model(whichModel).shaderList(index).emissive

Description

3D #standard shader property; adds light to the shader independently of the lighting in the scene. For example, a model using a shader whose emissive property is set to \textit{rgb}(255, 255, 255) will appear to be illuminated by a white light, even if there are no lights in the scene. The model will not, however, illuminate any other models or contribute any light to the scene.

The default value for this property is \textit{rgb}(0, 0, 0).

Example

This statement sets the emissive property of the shader named Globe to \textit{rgb}(255, 0, 0).

Models using this shader will appear to be illuminated by a red light:

member("MysteryWorld").shader("Globe").emissive = \textit{rgb}(255, 0, 0)

silhouettes

emitter

Usage

member(whichCastmember).modelResource(whichModelResource).
  \textit{emitter.numParticles}
member(whichCastmember).modelResource(whichModelResource).
  \textit{emitter.mode}
member(whichCastmember).modelResource(whichModelResource).
  \textit{emitter.loop}
member(whichCastmember).modelResource(whichModelResource).
  \textit{emitter.direction}
member(whichCastmember).modelResource(whichModelResource).
  \textit{emitter.region}
member(whichCastmember).modelResource(whichModelResource).
  \textit{emitter.distribution}
member(whichCastmember).modelResource(whichModelResource).
  \textit{emitter.angle}
member(whichCastmember).modelResource(whichModelResource).
  \textit{emitter.path}
member(whichCastmember).modelResource(whichModelResource).
  \textit{emitter.pathStrength}
member(whichCastmember).modelResource(whichModelResource).
  \textit{emitter.minSpeed}
member(whichCastmember).modelResource(whichModelResource).
  \textit{emitter.maxSpeed}

Description

3D particle system element; controls the initial propulsion of particles from a model resource whose type is \textit{#particle}. 
The “See also” section of this entry contains a complete list of emitter properties. For more information, see the individual property entries.

See also
numParticles, loop (emitter), direction, distribution, region, angle (3D), path (3D), pathStrength, minSpeed, maxSpeed

emulateMultibuttonMouse

Usage
-- Lingo syntax
_player.emulateMultibuttonMouse

// JavaScript syntax
_player.emulateMultibuttonMouse;

Description
Player property; determines whether a movie interprets a mouse click with the Control key pressed on the Macintosh the same as a right mouse click in Windows (TRUE) or not (FALSE, default). Read/write.

Right-clicking has no direct Macintosh equivalent.

Setting this property to TRUE lets you provide consistent mouse button responses for cross-platform movies.

Example
The following sets the emulateMultibuttonMouse property to TRUE:
-- Lingo syntax
_player.emulateMultibuttonMouse = TRUE

// JavaScript syntax
_player.emulateMultibuttonMouse = true;

See also
Player

enabled

Usage
the enabled of menuItem whichItem of menu whichMenu

Description
Menu item property; determines whether the menu item specified by whichItem is displayed in plain text and is selectable (TRUE, default) or appears dimmed and is not selectable (FALSE).

The expression whichItem can be either a menu item name or a menu item number. The expression whichMenu can be either a menu name or a menu number.

The enabled property can be tested and set.

Note: Menus are not available in Shockwave Player.
Example

This handler enables or disables all the items in the specified menu. The argument theMenu specifies the menu; the argument Setting specifies TRUE or FALSE. For example, the calling statement ableMenu ("Special", FALSE) disables all the items in the Special menu.

```on ableMenu theMenu, vSetting
    set n = the number of menuItems of menu theMenu
    repeat with i = 1 to n
        set the enabled of menuItem i of menu theMenu to vSetting
    end repeat
end ableMenu```

See also

`name (menu property), number (menus), checkMark, script, number (menu items)`

enabled (collision)

Usage

`member(whichCastmember).model(whichModel).collision.enabled`

Description

3D collision property; allows you to get or set whether (TRUE) or not (FALSE) collisions are detected on models. Setting this property to FALSE temporarily disables the collision modifier without removing it from the model.

The default setting for this property is TRUE.

Example

This statement activates the collision modifier for the model box:

```member("3d world").model("box").collision.enabled = TRUE```

See also

`addModifier, collision (modifier), modifier`

enabled (fog)

Usage

```member(whichCastmember).camera(whichCamera).fog.enabled
sprite(whichSprite).camera(index)).fog.enabled```

Description

3D camera property; indicates whether the camera adds fog to the view from the camera. The default setting for this property is FALSE.

Example

This statement creates fog in the view from the camera named BayView:

```member("MyYard").camera("BayView").fog.enabled = TRUE```

See also

`fog`
enabled (sds)

Usage
   member(whichCastmember).model(whichModel).sds.enabled

Description
   3D sds modifier property; indicates whether the sds modifier attached to a model is used by
   the model.
   The default setting for this property is TRUE.
   An attempt to add the sds modifier to a model that already has the inker or toon modifier
   attached fails without an error message. Likewise, an attempt to add the inker or toon modifier
   to a model that already has the sds modifier attached also fails without an error message. Be
   careful when using the sds modifier with the lod modifier. For more information, see the sds
   (modifier) entry.

Example
   This statement turns on the sds modifier attached to the model Baby:
   member("Scene").model("Baby").sds.enabled = TRUE

See also
   sds (modifier), modifier, addModifier

enableFlashLingo

Usage
   -- Lingo syntax
   _movie.enableFlashLingo

   // JavaScript syntax
   _movie.enableFlashLingo;

Description
   Movie property; determines whether a sprite with Flash content can make any direct scripting
   callbacks when using the Flash getURL() method. Read/write.
   The Flash getURL() method loads a new URL into a blank browser window.
   If enableFlashLingo is set to TRUE, a sprite with Flash content can execute any valid script
   command (subject to standard Shockwave Player-safe rules) when getURL() is called.
   If enableFlashLingo is set to FALSE, a sprite with Flash content is prevented from executing
   script commands when getURL() is called. The default value of this property is FALSE.
   This property is useful when creating a movie that displays Flash content of unknown origin,
   such as in a projector that browses a system folder for SWF files, or a movie with Shockwave
   content that accepts a URL for a SWF file from an end user.

Example
   This statement sets the enableFlashLingo property to TRUE:
   -- Lingo syntax
   _movie.enableFlashLingo = TRUE
// JavaScript syntax
_movie.enableFlashLingo = true;

See also
Movie

endAngle

Usage
member(whichCastmember).modelResource(whichModelResource).\endAngle

Description
3D #cylinder or #sphere model resource property; indicates how much of the sphere or cylinder is drawn.

The surface of a sphere is generated by sweeping a 2D half circle arc around the sphere's Y axis from startAngle to endAngle. If startAngle is set to 0 and endAngle is set to 360, the result is a complete sphere. To draw a section of a sphere, set endAngle to a value less than 360.

The surface of a cylinder is generated by sweeping a 2D line around the sphere's Y axis from startAngle to endAngle. If startAngle is set to 0 and endAngle is set to 360, the result is a complete cylinder. To draw a section of a cylinder, set endAngle to a value less than 360.

The default setting for this property is 360.

Example
For this example, assume that the cast member named MyMember contains a model that uses the model resource named Sphere4, whose endAngle value is 310, leaving an opening of 50°. The handler closeSphere closes that opening in a way that makes it look like it is sliding shut. The repeat loop changes the endAngle value of the sphere 1° at a time. The updateStage command in the repeat loop forces the Stage to redraw after every 1° increment.

on closeSphere
  MyAngle = member("MyMember").modelResource("Sphere4").endAngle
  repeat with r = 1 to 50
    MyAngle = MyAngle + 1
    member("MyMember").modelResource("Sphere4").endAngle = MyAngle
    updateStage
  end
end repeat

See also
state (3D)
**endColor**

**Usage**

-- Lingo syntax
memberObjRef.endColor

// JavaScript syntax
memberObjRef.endColor;

**Description**

Vector shape cast member property; the ending color of a gradient shape's fill specified as an RGB value.

endColor is only valid when the fillMode is set to #gradient, and the starting color is set with fillColor.

This property can be tested and set.

To see an example of endColor used in a completed movie, see the Vector Shapes movie in the Learning/Lingo Examples folder inside the Director application folder.

**See also**

color(), fillColor, fillMode

**endFrame**

**Usage**

-- Lingo syntax
spriteObjRef.endFrame

// JavaScript syntax
spriteObjRef.endFrame;

**Description**

Sprite property; returns the frame number of the end frame of the sprite span. Read-only.

This property is useful in determining the span in the Score of a particular sprite.

This property is available only in a frame that contains the sprite. It cannot be applied to sprites in different frames of the movie.

**Example**

This statement output reports the ending frame of the sprite in channel 5 in the Message window:

-- Lingo syntax
put(sprite(5).endFrame)

// JavaScript syntax
put(sprite(5).endFrame);

**See also**

Sprite, startFrame
endTime

Usage

-- Lingo syntax
soundChannelObjRef.endTime

// JavaScript syntax
soundChannelObjRef.endTime;

Description

Sound Channel property; specifies the end time of the currently playing, paused, or queued sound. Read/write.

The end time is the time within the sound member when it will stop playing. It's a floating-point value, allowing for measurement and control of sound playback to fractions of milliseconds. The default value is the normal end of the sound.

This property may be set to a value other than the normal end of the sound only when passed as a parameter with the queue() or setPlayList() methods.

Example

These statements check whether the sound member Jingle is set to play all the way through in sound channel 1:

-- Lingo syntax
if (sound(1).startTime > 0 and sound(1).endTime < member("Jingle").duration) \ 
then
    _player.alert("Not playing the whole sound.");
end if

// JavaScript syntax
if (sound(1).startTime > 0 && sound(1).endTime < member("Jingle").duration) { 
    _player.alert("Not playing the whole sound.");
}

See also

queue(). setPlayList(). Sound Channel

environmentPropList

Usage

-- Lingo syntax
_system.environmentPropList

// JavaScript syntax
_system.environmentPropList;

Description

System property; contains a list with information about the environment under which the Director content is currently running. Read-only.

This design enables Macromedia to add information to the environmentPropList property in the future, without affecting existing movies.
The information is in the form of property and value pairs for that area.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&amp;#shockMachine</td>
<td>Integer TRUE or FALSE value indicating whether the movie is playing in ShockMachine.</td>
</tr>
<tr>
<td>&amp;#shockMachineVersion</td>
<td>String indicating the installed version number of ShockMachine.</td>
</tr>
<tr>
<td>&amp;platform</td>
<td>String containing &quot;Macintosh,PowerPC&quot;, or &quot;Windows,32&quot;. This is based on the current OS and hardware that the movie is running under.</td>
</tr>
<tr>
<td>&amp;runMode</td>
<td>String containing &quot;Author&quot;, &quot;Projector&quot;, or &quot;Plugin&quot;. This is based on the current application that the movie is running under.</td>
</tr>
<tr>
<td>&amp;colorDepth</td>
<td>Integer representing the bit depth of the monitor the Stage appears on. Possible values are 1, 2, 4, 8, 16, or 32.</td>
</tr>
<tr>
<td>&amp;internetConnected</td>
<td>Symbol indicating whether the computer the movie is playing on has an active Internet connection. Possible values are #online and #offline.</td>
</tr>
<tr>
<td>&amp;uiLanguage</td>
<td>String indicating the language the computer is using to display its user interface. This can be different from the &amp;osLanguage on computers with specific language kits installed.</td>
</tr>
<tr>
<td>&amp;osLanguage</td>
<td>String indicating the native language of the computer's operating system.</td>
</tr>
<tr>
<td>&amp;productBuildVersion</td>
<td>String indicating the internal build number of the playback application.</td>
</tr>
</tbody>
</table>

The properties contain exactly the same information as the properties and functions of the same name.

Example

This statement displays the environment list in the Message window:

```-- Lingo syntax
put(_system.environmentPropList)
```

```// JavaScript syntax
put(_system.environmentPropList);
```

See also

System

error

Usage

member(whichCastmember).model(whichModel).sds.error

Description

3D #sds modifier property; indicates the percentage of error tolerated by the modifier when synthesizing geometric detail in models.

This property works only when the modifier's subdivision property is set to #adaptive. The tension and depth (3D) properties of the modifier combine with the error property to control the amount of subdivision performed by the modifier.
Example

The following statement sets the `error` property of the `#sds` modifier of the model named Baby to 0. If the modifier's `tension` setting is low, its `depth` setting is high, and its `subdivision` setting is `#adaptive`, this will cause a very pronounced effect on Baby's geometry.

```lingo
member("Scene").model("Baby").sds.error = 0
```

See also

`sds (modifier), subdivision, depth (3D), tension`

eventPassMode

Usage

```lingo
-- Lingo syntax
memberOrSpriteObjRef.eventPassMode

// JavaScript syntax
memberOrSpriteObjRef.eventPassMode;
```

Description

Flash cast member property and sprite property; controls when a Flash movie passes mouse events to behaviors that are attached to sprites that lie underneath the flash sprite. The `eventPassMode` property can have these values:

- `#passAlways` (default)—Always passes mouse events.
- `#passButton`—Passes mouse events only when a button in the Flash movie is clicked.
- `#passNotButton`—Passes mouse events only when a nonbutton object is clicked.
- `#passNever`—Never passes mouse events.

This property can be tested and set.

Example

The following frame script checks to see whether the buttons in a Flash movie sprite are currently enabled, and if so, sets `eventPassMode` to `#passNotButton`; if the buttons are disabled, the script sets `eventPassMode` to `#passAlways`. The effect of this script is the following:

- Mouse events on nonbutton objects always pass to sprite scripts.
- Mouse events on button objects are passed to sprite scripts when the buttons are disabled.
  When the buttons are enabled, mouse events on buttons are stopped.

```lingo
-- Lingo syntax
on enterFrame
  if sprite(5).buttonsEnabled = TRUE then
    sprite(5).eventPassMode = #passNotButton
  else
    sprite(5).eventPassMode = #passAlways
  end if
end
```

```javascript
function enterFrame() {
  var btEn = sprite(5).buttonsEnabled;
  if (btEn = 1) {
    sprite(5).eventPassMode = symbol("passNotButton");
  } else {
    sprite(5).eventPassMode = symbol("passAlways");
  }
}
```
exitLock

Usage

-- Lingo syntax
_movie.exitLock

// JavaScript syntax
_movie.exitLock;

Description

Movie property; determines whether a user can quit to the Windows desktop or Macintosh Finder from projectors (FALSE, default) or not (TRUE). Read/write.

The user can quit to the desktop by pressing Control+period (Windows) or Command+period (Macintosh), Control+Q (Windows) or Command+Q (Macintosh), or Control+W (Windows) or Command+W (Macintosh); the Escape key is also supported in Windows.

Example

This statement sets the exitLock property to TRUE:

-- Lingo syntax
_movie.exitLock = TRUE

// JavaScript syntax
_movie.exitLock = true;

Assuming that exitLock is set to TRUE, nothing occurs automatically when the Control+period/Q/W, Esc, or Command+period/Q/W keys are used. This handler checks keyboard input for keys to exit and takes the user to a custom quit sequence:

-- Lingo syntax
on checkExit
  if ((_key.commandDown) and (_key.key = "." or _key.key = "q") and (_movie.exitLock = TRUE)) then _movie.go("quit sequence")
end checkExit

// JavaScript syntax
function checkExit() {
  if ((_key.commandDown) && (_key.key == "." || _key.key == "q") && (_movie.exitLock == true)) {
    _movie.go("quit sequence");
  }
}

See also

Movie

externalParamCount

Usage

-- Lingo syntax
_player.externalParamCount

// JavaScript syntax
_player.externalParamCount;
Description

Player property; returns the number of parameters that an HTML <EMBED> or <OBJECT> tag is passing to a movie with Shockwave content. Read-only.

This property is valid only for movies with Shockwave content that are running in a browser. It doesn't work for movies during authoring or for projectors.

For more information about the valid external parameters, see externalParamName() and externalParamValue().

Example

This handler determines whether an <OBJECT> or <EMBED> tag is passing any external parameters to a movie with Shockwave content and runs Lingo statements if parameters are being passed:

```
-- Lingo syntax
if (_player.externalParamCount > 0) then
    -- perform some action
end if

// JavaScript syntax
if (_player.externalParamCount > 0) {
    // perform some action;
}
```

See also

externalParamName(), externalParamValue(), Player

face

Usage

```
member(whichCastmember).modelResource(whichModelResource).\face.count
member(whichCastmember).modelResource(whichModelResource).\face[index].colors
member(whichCastmember).modelResource(whichModelResource).\face[index].normals
member(whichCastmember).modelResource(whichModelResource).\face[index].shader
member(whichCastmember).modelResource(whichModelResource).\face[index].textureCoordinates
member(whichCastmember).modelResource(whichModelResource).\face[index].vertices
member(whichCastmember).model(whichModel).meshdeform.\face.count
member(whichCastmember).model(whichModel).meshdeform.\mesh[index].face.count
member(whichCastmember).model(whichModel).meshdeform.\mesh[index].face[faceIndex]
member(whichCastmember).model(whichModel).meshdeform.\mesh[index].face[faceIndex].neighbor[neighborIndex]
```

Description

3D #mesh model resource and meshdeform modifier property. All model resources are meshes composed of triangles. Each triangle is a face.
You can access the properties of the faces of model resources whose type is #mesh. Changes to any of these properties do not take effect until you call the build() command.

**Note:** For detailed information about the following properties, see the individual property entries.

- **count** indicates the number of triangles in the mesh.
- **colors** indicates which indices in the color list of the model resource to use for each of the vertices of the face.
- **normals** indicates which indices in the normal list of the model resource to use for each of the vertices of the face.
- **shadowPercentage** identifies the shader used when the face is rendered.
- **textureCoordinates** indicates which indices in the texture coordinate list of the model resource to use for each of the vertices of the face.
- **vertices** indicates which indices in the vertex list of the model resource to use to define the face.

See the entry for meshDeform for descriptions of its face properties.

See also
- build(), newMesh, meshDeform (modifier)

**face[]**

**Usage**
```lisp
member(whichCastmember).model(whichModel).meshdeform.\n    mesh[meshIndex].face[faceIndex]
```

**Description**

3D meshDeform modifier property; indicates which indices in the vertex list of the model resource were used to define the face.

This property can be tested but not set. You can specify the vertices of a face of the #mesh model resource by setting its vertexList and vertices properties and calling the build command.

**Example**

This statement shows that the first face of the first mesh of the model named Floor is defined by the first three vectors in the vertex list of the model resource used by Floor:
```lisp
put member("Scene").model("Floor").meshdeform.mesh[1].face[1]  
-- [1, 2, 3]
```

See also
- meshDeform (modifier), face, vertexList (mesh deform), vertices
远 (烟雾)

**Usage**

```lingo
member(whichCastmember).camera(whichCamera).fog.far
sprite(whichSprite).camera(index).fog.far
```

**Description**

3D 相机属性；表示在相机的 `fog.enabled` 属性设为 `TRUE` 时，烟雾达到最大密度的距离，以世界单位计算。

默认值为 1000。

**Example**

以下语句将名为 BayView 的相机的远距离属性设置为 5000。

如果烟雾的 `enabled` 属性设为 `TRUE`，烟雾将在 5000 世界单位处最浓。

```lingo
member("MyYard").camera("BayView").fog.far = 5000
```

**See also**

`fog, 近 (烟雾)`

**fieldOfView**

**Usage**

```lingo
-- Lingo syntax
spriteObjRef.fieldOfView
```

```javascript
spriteObjRef.fieldOfView;
```

**Description**

QTVR 静态属性；返回指定静止的当前视野角度，以度为单位。

此属性可以获取和设置。

**fieldOfView (3D)**

**Usage**

```lingo
member(whichCastmember).camera(whichCamera).fieldOfView
sprite(whichSprite).camera(index).fieldOfView
```

**Description**

3D 相机属性；表示从相机到顶部和底部投影平面的两条射线形成的角：一个来自相机到投影平面上方，另一个从相机到投影平面下方。

3D 世界中的模型的图像映射到投影平面上，该平面像电影放映机前的屏幕一样，位于相机之前。投影平面的顶部和底部由 `fieldOfView` 属性定义。

但在喷绘过程中，喷绘并不因 `fieldOfView` 属性的值而改变。相反，投影平面图像的尺寸将根据喷绘的尺寸变化。
The value of this property is meaningful only when the value of the camera’s `projection` property is set to `#perspective`. When the `projection` property is set to `#orthographic`, use the camera’s `orthoHeight` property to define the top and bottom of the projection plane.

The default setting for this property is 30.0.

**Example**

This statement sets the `fieldOfView` property of camera 1 to 90:

```lingo
member("3d world").camera[1].fieldOfView = 90
```

**See also**

`orthoHeight`

### fileFreeSize

**Usage**

- **Lingo syntax**
  ```lingo
  _movie.fileFreeSize
  ```

- **JavaScript syntax**
  ```javascript
  _movie.fileFreeSize;
  ```

**Description**

Movie property; returns the number of unused bytes in the current movie caused by changes to the cast libraries and cast members within a movie. Read-only.

The `Save` and `Compact` and `Save As` commands rewrite the file to delete this free space.

When the movie has no unused space, `fileFreeSize` returns 0.

**Example**

This statement displays the number of unused bytes that are in the current movie:

```lingo
-- Lingo syntax
put(_movie.fileFreeSize)
```

```javascript
// JavaScript syntax
put(_movie.fileFreeSize);
```

**See also**

`Movie`

### fileName (Cast)

**Usage**

- **Lingo syntax**
  ```lingo
  castObjRef.fileName
  ```

- **JavaScript syntax**
  ```javascript
  castObjRef.fileName;
  ```

**Description**

Cast library property; returns or sets the filename of a cast library. Read-only for internal cast libraries, read/write for external cast libraries.
For external cast libraries, `fileName` returns the cast’s full pathname and filename.

For internal cast libraries, `fileName` returns a value depending on which internal cast library is specified.

- If the first internal cast library is specified, `fileName` returns the name of the movie.
- If any other internal cast library is specified, `fileName` returns an empty string.

This property accepts URLs as references. However, to use a cast library from the Internet and minimize download time, use the `downloadNetThing()` or `preloadNetThing()` methods to download the cast’s file to a local disk, and then set `fileName` to the file on the disk.

If a movie sets the filename of an external cast, do not use the Duplicate cast members for Faster Loading option in the Project Options dialog box.

**Example**

This statement displays the pathname and filename of the Buttons external cast in the Message window:

```-- Lingo syntax
trace(castLib("Buttons").fileName)
```

```
// JavaScript syntax
trace(castLib("Buttons").fileName);
```

This statement sets the filename of the Buttons external cast to Content.cst:

```-- Lingo syntax
castLib("Buttons").fileName = _movie.path & "Content.cst"
```

```
// JavaScript syntax
castLib("Buttons").fileName = _movie.path + "Content.cst";
```

The movie then uses the external cast file Content.cst as the Buttons cast.

These statements download an external cast from a URL to the Director application folder and then make that file the external cast named Cast of Thousands:

```-- Lingo syntax
downloadNetThing("http://wwwcbDeMille.com/Thousands.cst", \
_player.applicationPath & "Thousands.cst")
castLib("Cast of Thousands").fileName = _player.applicationPath & \
"Thousands.cst"
```

```
// JavaScript syntax
downloadNetThing("http://wwwcbDeMille.com/Thousands.cst", \
_player.applicationPath + "Thousands.cst");
castLib("Cast of Thousands").fileName = _player.applicationPath + \
"Thousands.cst";
```

**See also**

`Cast Library`, `downloadNetThing`, `preloadNetThing()`
fileName (Member)

Usage

-- Lingo syntax
memberObjRef.fileName

// JavaScript syntax
memberObjRef.fileName;

Description

Member property; refers to the name of the file assigned to a linked cast member. Read/write.
This property is useful for switching the external linked file assigned to a cast member while a
movie plays, similar to the way you can switch cast members. When the linked file is in a different
folder than the movie, you must include the file's pathname.
You can also make unlinked media linked by setting the filename of those types of members that
support linked media.
This property also accepts URLs as a reference. However, to use a file from a URL and minimize
download time, use the downloadNetThing() or preloadNetThing() methods to download the
file to a local disk first and then set the fileName property to the file on the local disk.
After the filename is set, Director uses that file the next time the cast member is used.

Example

This statement links the QuickTime movie “ChairAnimation” to cast member 40:

-- Lingo syntax
member(40).fileName = "ChairAnimation"

// JavaScript syntax
member(40).fileName = "ChairAnimation";

These statements download an external file from a URL to the Director application folder and
make that file the media for the sound cast member Norma Desmond Speaks:

-- Lingo syntax
downloadNetThing("http://wwwcbDeMille.com/Talkies.AIF", 
_player.applicationPath & "Talkies.AIF")
member("Norma Desmond Speaks").fileName = _player.applicationPath & 
"Talkies.AIF"

// JavaScript syntax
downloadNetThing("http://wwwcbDeMille.com/Talkies.AIF", 
_player.applicationPath + "Talkies.AIF");
member("Norma Desmond Speaks").fileName = _player.applicationPath + 
"Talkies.AIF";

See also

downloadNetThing, Member, preloadNetThing()
**fileName (Window)**

**Usage**

-- Lingo syntax
windowObjRef.fileName

// JavaScript syntax
windowObjRef.fileName;

**Description**

Window property; refers to the filename of the movie assigned to a window. Read/write.

When the linked file is in a different folder than the movie, you must include the file's pathname.

To be able to play the movie in a window, you must set the `fileName` property to the movie's filename.

The `fileName` property accepts URLs as a reference. However, to use a movie file from a URL and minimize the download time, use the `downloadNetThing()` or `preloadNetThing()` methods to download the movie file to a local disk first and then set `fileName` property to the file on the local disk.

**Example**

This statement assigns the file named Control Panel to the window named Tool Box:

-- Lingo syntax
window("Tool Box").fileName = "Control Panel"

// JavaScript syntax
window("Tool Box").fileName = "Control Panel";

This statement displays the filename of the file assigned to the window named Navigator:

-- Lingo syntax
trace(window("Navigator").fileName)

// JavaScript syntax
trace(window("Navigator").fileName);

These statements download a movie file from a URL to the Director application folder and then assign that file to the window named My Close Up:

-- Lingo syntax
downloadNetThing("http://www.cbDeMille.com/Finale.DIR", _player.applicationPath & "Finale.DIR")
window("My Close Up").fileName = _player.applicationPath & "Finale.DIR"

// JavaScript syntax
downloadNetThing("http://www.cbDeMille.com/Finale.DIR", _player.applicationPath + "Finale.DIR");
window("My Close Up").fileName = _player.applicationPath + "Finale.DIR";

**See also**

downloadNetThing, preloadNetThing(), Window
**fileSize**

**Usage**

```lingo
_movie.fileSize
```

```javascript
_movie.fileSize;
```

**Description**

Movie property; returns the number of bytes in the current movie saved on disk. Read-only.

This is the same number returned when selecting File Properties in Windows or Get Info in the Macintosh Finder.

**Example**

This statement displays the number of bytes in the current movie:

```lingo
put(_movie.fileSize)
```

```javascript
put(_movie.fileSize);
```

**See also**

`Movie`

**FileVersion**

**Usage**

```lingo
_movie.fileVersion
```

```javascript
_movie.fileVersion;
```

**Description**

Movie property; indicates the version, as a string, of Director in which the movie was last saved. Read-only.

**Example**

This statement displays the version of Director that last saved the current movie:

```lingo
put(_movie.fileVersion)
```

```javascript
put(_movie.fileVersion);
```

**See also**

`Movie`
fillColor

Usage

-- Lingo syntax
memberObjRef.fillColor

// JavaScript syntax
memberObjRef.fillColor;

Description

Vector shape cast member property; the color of the shape's fill specified as an RGB value.

It's possible to use fillColor when the fillMode property of the shape is set to #solid or #gradient, but not if it is set to #none. If the fillMode is #gradient, fillColor specifies the starting color for the gradient. The ending color is specified with endColor.

This property can be tested and set.

To see an example of fillColor used in a completed movie, see the Vector Shapes movie in the Learning/Lingo Examples folder inside the Director application folder.

Example

This statement sets the fill color of the member Archie to a new RGB value:

-- Lingo syntax
member("Archie").fillColor = color(24,15,153)

// JavaScript syntax
member("Archie").fillColor = color(24,15,153);

See also

endColor, fillMode

fillCycles

Usage

-- Lingo syntax
memberObjRef.fillCycles

// JavaScript syntax
memberObjRef.fillCycles;

Description

Vector shape cast member property; the number of fill cycles in a gradient vector shape's fill, as specified by an integer value from 1 to 7.

This property is valid only when the fillMode property of the shape is set to #gradient.

This property can be tested and set.

To see an example of fillCycles used in a completed movie, see the Vector Shapes movie in the Learning/Lingo Examples folder inside the Director application folder.
Example

This statement sets the fillCycles of member Archie to 3:

-- Lingo syntax
member("Archie").fillCycles = 3
// JavaScript syntax
member("Archie").fillCycles = 3;

See also
endColor, fillColor, fillMode

fillDirection

Usage

-- Lingo syntax
memberObjRef.fillDirection

// JavaScript syntax
memberObjRef.fillDirection;

Description

Vector shape cast member property; specifies the amount in degrees to rotate the fill of the shape. This property is only valid when the fillMode property of the shape is set to #gradient. This property can be tested and set.

To see an example of fillDirection used in a completed movie, see the Vector Shapes movie in the Learning/Lingo Examples folder inside the Director application folder.

See also
fillMode

filled

Usage

member(whichCastMember).filled
the filled of member whichCastMember

Description

Shape cast member property; indicates whether the specified cast member is filled with a pattern (TRUE) or not (FALSE).

Example

The following statements make the shape cast member Target Area a filled shape and assign it the pattern numbered 1, which is a solid color:

member("Target Area").filled = TRUE
member("Target Area").pattern = 1

See also
fillColor, fillMode
fillMode

Usage
-- Lingo syntax
memberObjRef.fillMode

// JavaScript syntax
memberObjRef.fillMode;

Description
Vector shape cast member property; indicates the fill method for the shape, using the following possible values:
• #none—The shape is transparent
• #solid—The shape uses a single fill color
• #gradient—The shape uses a gradient between two colors
This property can be tested and set when the shape is closed; open shapes have no fill.

To see an example of fillMode used in a completed movie, see the Vector Shapes movie in the Learning/Lingo Examples folder inside the Director application folder.

Example
This statement sets the fillMode of member Archie to gradient:
-- Lingo syntax
member("Archie").fillMode = #gradient

// JavaScript syntax
member("Archie").fillMode = symbol("gradient");

See also
dEndColor, fillColor

fillOffset

Usage
-- Lingo syntax
memberObjRef.fillOffset

// JavaScript syntax
memberObjRef.fillOffset;

Description
Vector shape cast member property; specifies the horizontal and vertical amount in pixels (within the defaultRect space) to offset the fill of the shape.

This property is only valid when the fillMode property of the shape is set to #gradient, but can be both tested and set.

To see an example of fillOffset used in a completed movie, see the Vector Shapes movie in the Learning/Lingo Examples folder inside the Director application folder.
Example

This statement changes the fill offset of the vector shape cast member miette to a horizontal offset of 33 pixels and a vertical offset of 27 pixels:

-- Lingo syntax
member("miette").fillOffset = point(33, 27)

// JavaScript syntax
member("miette").fillOffset = point(33, 27);

See also
defaultRect, fillMode

fillScale

Usage

-- Lingo syntax
memberObjRef.fillScale

// JavaScript syntax
memberObjRef.fillScale;

Description

Vector shape cast member property; specifies the amount to scale the fill of the shape. This property is referred to as “spread” in the vector shape window. This property is only valid when the fillMode property of the shape is set to #gradient, but can be both tested and set.

To see an example of fillScale used in a completed movie, see the Vector Shapes movie in the Learning/Lingo Examples folder inside the Director application folder.

Example

This statement sets the fillScale of member Archie to 33:

-- Lingo syntax
member("Archie").fillScale = 33.00

// JavaScript syntax
member("Archie").fillScale = 33.00;

See also

fillMode
**firstIndent**

**Usage**

```-- Lingo syntax
chunkExpression.firstIndent
```

```// JavaScript syntax
chunkExpression.firstIndent;
```

**Description**

Text cast member property; contains the number of pixels the first indent in `chunkExpression` is offset from the left margin of `chunkExpression`.

The value is an integer: less than 0 indicates a hanging indent, 0 is no indentation, and greater than 0 is a normal indentation.

This property can be tested and set.

**Example**

This statement sets the indent of the first line of member Desk to 0 pixels:

```--Lingo syntax
member("Desk").firstIndent = 0
```

```// JavaScript syntax
member("Desk").firstIndent = 0;
```

**See also**

`leftIndent`, `rightIndent`

**fixedLineSpace**

**Usage**

```-- Lingo syntax
chunkExpression.fixedLineSpace
```

```// JavaScript syntax
chunkExpression.fixedLineSpace;
```

**Description**

Text cast member property; controls the height of each line in the `chunkExpression` portion of the text cast member.

The value itself is an integer, indicating height in absolute pixels of each line.

The default value is 0, which results in natural height of lines.

**Example**

This statement sets the height in pixels of each line of member Desk to 24:

```--Lingo syntax
member("Desk").fixedLineSpace = 24
```

```// JavaScript syntax
member("Desk").fixedLineSpace = 24;
```
fixedRate

Usage

-- Lingo syntax
memberOrSpriteObjRef.fixedRate

// JavaScript syntax
memberOrSpriteObjRef.fixedRate;

Description

Cast member property and sprite property; controls the frame rate of a Flash movie or animated GIF. The fixedRate property can have integer values. The default value is 15.

This property is ignored if the sprite's playbackMode property is anything other than #fixed.

This property can be tested and set.

Example

The following handler adjusts the frame rate of a Flash movie sprite. As parameters, the handler accepts a sprite reference, an indication of whether to speed up or slow down the Flash movie, and the amount to adjust the speed.

-- Lingo syntax
on adjustFixedRate(whichSprite, adjustType, howMuch)
    case adjustType of
        #faster:
            sprite(whichSprite).fixedRate = sprite(whichSprite).fixedRate + howMuch
        #slower:
            sprite(whichSprite).fixedRate = sprite(whichSprite).fixedRate - howMuch
    end case
end

// JavaScript syntax
function adjustFixedRate(whichSprite, adjustType, howMuch) {
    switch(adjustType) {
        case "faster":
            sprite(whichSprite).fixedRate = sprite(whichSprite).fixedRate + howMuch;
            break;
        case "slower":
            sprite(whichSprite).fixedRate = sprite(whichSprite).fixedRate - howMuch;
            break;
    }
}

See also

playBackMode
fixStageSize

Usage

-- Lingo syntax
_movie.fixStageSize

// JavaScript syntax
_movie.fixStageSize;

Description

Movie property; determines whether the Stage size remains the same when you load a new movie (TRUE, default), or not (FALSE), regardless of the Stage size saved with that movie, or the setting for the centerStage. Read/write.

The fixStageSize property cannot change the Stage size for a movie that is currently playing.

Example

The following statement determines whether the fixStageSize property is turned on. If fixStageSize is FALSE, it sends the playhead to a specified frame.

-- Lingo syntax
if (_movie.fixStageSize = FALSE) then
    _movie.go("proper size")
end if

// JavaScript syntax
if (_movie.fixStageSize == false) {
    _movie.go("proper size");
}

This statement sets the fixStageSize property to the opposite of its current setting:

-- Lingo syntax
_movie.fixStageSize = not(_movie.fixStageSize)

// JavaScript syntax
_movie.fixStageSize = !(_movie.fixStageSize);

See also

centerStage, Movie

flashRect

Usage

-- Lingo syntax
memberObjRef.flashRect

// JavaScript syntax
memberObjRef.flashRect;

Description

Cast member property; indicates the size of a Flash movie or vector shape cast member as it was originally created. The property values are indicated as a Director rectangle: for example, rect(0,0,32,32).
For linked Flash cast members, the `FlashRect` member property returns a valid value only when the cast member's header has finished loading into memory.

This property can be tested but not set.

**Example**

This sprite script resizes a Flash movie sprite so that it is equal to the original size of its Flash movie cast member:

```-- Lingo syntax
property spriteNum

on beginSprite me
  sprite(spriteNum).rect = sprite(spriteNum).member.FlashRect
end

// JavaScript syntax
function beginSprite() {
  sprite(this.spriteNum).rect = sprite(this.spriteNum).member.FlashRect;
}
```

See also: `defaultRect`, `defaultRectMode`, `state (Flash, SWA)`

---

**flat**

**Usage**

- `member(whichCastmember).shader(whichShader).flat`
- `member(whichCastmember).model(whichModel).shader.flat`
- `member(whichCastmember).model(whichModel).shaderList[index].flat`

**Description**

3D `#standard` shader property; indicates whether the mesh should be rendered with flat shading (`TRUE`) or Gouraud shading (`FALSE`). Flat shading uses one color per face of the mesh. The color used for the face is the color of its first vertex. Flat shading is faster than Gouraud shading.

Gouraud shading assigns a color to each vertex of a face and interpolates the colors across the face in a gradient. Gouraud shading requires more time and calculation, but creates a smoother surface.

The default value for this property is `FALSE`.

**Example**

The following statement sets the `flat` property of the shader named `Wall` to `TRUE`. The mesh of a model that uses this shader will be rendered with one color per face.

```member("MysteryWorld").shader("Wall").flat = TRUE```

See also: `mesh (property), colors, vertices, generateNormals()`
flipH

Usage

-- Lingo syntax
spriteObjRef.flipH

// JavaScript syntax
spriteObjRef.flipH;

Description

Sprite property; indicates whether a sprite's image has been flipped horizontally on the Stage (TRUE) or not (FALSE). Read-only.

The image itself is flipped around its registration point.

This means any rotation or skew remains constant; only the image data itself is flipped.

Example

This statement displays the flipH of sprite 5:

-- Lingo syntax
put(sprite(5).flipH)

// JavaScript syntax
put(sprite(5).flipH);

See also

flipV, rotation, skew, Sprite

flipV

Usage

-- Lingo syntax
spriteObjRef.flipV

// JavaScript syntax
spriteObjRef.flipV;

Description

Sprite property; indicates whether a sprite's image has been flipped vertically on the Stage (TRUE) or not (FALSE). Read-only.

The image itself is flipped around its registration point.

This means any rotation or skew remains constant; only the image data itself is flipped.

Example

This statement displays the flipV of sprite 5:

-- Lingo syntax
put(sprite(5).flipV)

// JavaScript syntax
put(sprite(5).flipV);

See also

flipH, rotation, skew, Sprite
**floatPrecision**

**Usage**

the floatPrecision

**Description**

Movie property; rounds off the display of floating-point numbers to the number of decimal places specified. The value of floatPrecision must be an integer. The maximum value is 15 significant digits; the default value is 4.

The floatPrecision property determines only the number of digits used to display floating-point numbers; it does not change the number of digits used to perform calculations.

- If floatPrecision is a number from 1 to 15, floating-point numbers display that number of digits after the decimal point. Trailing zeros remain.
- If floatPrecision is zero, floating-point numbers are rounded to the nearest integer. No decimal points appear.
- If floatPrecision is a negative number, floating-point numbers are rounded to the absolute value for the number of decimal places. Trailing zeros are dropped.

This property can be tested and set.

**Example**

This statement rounds off the square root of 3.0 to three decimal places:

the floatPrecision = 3
x = sqrt(3.0)
put x
-- 1.732

This statement rounds off the square root of 3.0 to eight decimal places:

the floatPrecision = 8
put x
-- 1.73205081

**fog**

**Usage**

member(whichCastmember).camera(whichCamera).fog.color
sprite(whichSprite).camera(index).fog.color
member(whichCastmember).camera(whichCamera).fog.decayMode
sprite(whichSprite).camera(index).fog.decayMode
member(whichCastmember).camera(whichCamera).fog.enabled
sprite(whichSprite).camera(index).fog.enabled
member(whichCastmember).camera(whichCamera).fog.far
sprite(whichSprite).camera(index).fog.far
member(whichCastmember).camera(whichCamera).fog.near
sprite(whichSprite).camera(index).fog.near

**Description**

3D camera property; fog introduces a coloring and blurring of models that increases with distance from the camera. The effect is similar to real fog, except that it can be any color.

**See also**

color (fog), decayMode, enabled (fog), far (fog), near (fog)
folder

Usage
--- Lingo syntax
dvdObjRef.folder

// JavaScript syntax
dvdObjRef.folder;

Description
DVD property. Determines the pathname of the folder from which a DVD is playing. Read/write.
The pathname must be a string.

Example
This statement sets the pathname of the DVD folder:
--- Lingo syntax
member(2).folder = "C:\DVDs\"

// JavaScript syntax
member(2).folder = "C:\\DVDs\\";

See also
DVD

font

Usage
--- Lingo syntax
memberObjRef.font

// JavaScript syntax
memberObjRef.font;

Description
Text and field cast member property; determines the font used to display the specified cast
member and requires that the cast member contain characters, if only a space. The parameter
whichCastMember can be either a cast member name or number.

The font member property can be tested and set.
To see an example of font used in a completed movie, see the Text movie in the Learning/Lingo
Examples folder inside the Director application folder.

Example
This statement sets the variable named oldFont to the current font setting for the field cast
member Rokujo Speaks:
--- Lingo syntax
oldFont = member("Rokujo Speaks").font

// JavaScript syntax
var oldFont = member("Rokujo Speaks").font;

See also
text, alignment, fontSize, fontStyle, lineHeight
**fontStyle**

**Usage**

```-- Lingo syntax
memberObjRef.fontStyle
```

```// JavaScript syntax
memberObjRef.fontStyle;
```

**Description**

Field cast member property; determines the size of the font used to display the specified field cast member and requires that the cast member contain characters, if only a space. The parameter `whichCastMember` can be either a cast member name or number.

This property can be tested and set. When tested, it returns the height of the first line in the field. When set, it affects every line in the field.

To see an example of `fontStyle` used in a completed movie, see the Text movie in the Learning/Lingo Examples folder inside the Director application folder.

**Example**

This statement sets the variable named `oldSize` to the current `fontSize` of member setting for the field cast member Rokujo Speaks:

```--Lingo syntax
oldSize = member("Rokujo Speaks").fontSize
```

```// JavaScript syntax
var oldSize = member("Rokujo Speaks").fontSize;
```

This statement sets the third line of the text cast member myMenu to 24 points:

```member("myMenu").fontSize = 12
```

```// JavaScript syntax
member("myMenu").fontSize = 12;
```

**See also**

`text`, `alignment`, `font`, `fontStyle`, `lineHeight`

**fontStyle**

**Usage**

```-- Lingo syntax
memberObjRef.fontStyle
memberObjRef.char[whichChar].fontStyle
memberObjRef.line[whichLine].fontStyle
memberObjRef.word[whichWord].fontStyle
```

```// JavaScript syntax
memberObjRef.fontStyle;
memberObjRef.getPropRef("char", whichChar).fontStyle
memberObjRef.getPropRef("line", whichLine).fontStyle;
memberObjRef.getPropRef("word", whichWord).fontStyle;
```
Description

Cast member property; determines the styles applied to the font used to display the specified field cast member, character, line, word, or other chunk expression and requires that the field cast member contain characters, if only a space.

The value of the property is a string of styles delimited by commas. Lingo uses a font that is a combination of the styles in the string. The available styles are plain, bold, italic, underline, shadow, outline, and extended; on the Macintosh, condensed also is available.

Use the style plain to remove all currently applied styles. The parameter whichCastMember can be either a cast member name or number.

This property can be tested and set.

To see an example of fontStyle used in a completed movie, see the Text movie in the Learning/Lingo Examples folder inside the Director application folder.

Example

This statement sets the variable named oldStyle to the current fontStyle setting for the field cast member Rokujo Speaks:

--Lingo syntax
oldStyle = member("Rokujo Speaks").fontStyle

// JavaScript syntax
var oldStyle = member("Rokujo Speaks").fontStyle;

This statement sets the fontStyle member property for the field cast member Poem to bold italic:

--Lingo syntax
member("Poem").fontStyle = "bold, italic"

// JavaScript syntax
member("Poem").fontStyle = "bold, italic";

This statement sets the fontStyle property of the third word of the cast member Son’s Names to italic:

--Lingo syntax
member("Son’s Names").word[3].fontStyle = "italic"

// JavaScript syntax
member("Son’s Names").getPropRef("word", 3).fontStyle = "italic";

This statement sets the fontStyle member property of word 1 through word 4 of text member myNote to bold italic:

--Lingo syntax
member("myNote").word[1..4].fontstyle = "bold, italic"

// JavaScript syntax
for (var i = 1; i <= 4; i++) {
    member("myNote").getPropRef("word", i).fontStyle = "bold, italic";
}

See also
text, alignment, fontSize, font, lineHeight
**foreColor**

**Usage**

-- Lingo syntax
spriteObjRef.foreColor

// JavaScript syntax
spriteObjRef.foreColor;

**Description**

Sprite property; returns or sets the foreground color of a sprite. Read/write.

It is not recommended to apply this property to bitmap cast members deeper than 1-bit, as the results are difficult to predict.

It is recommended that the newer `color` property be used instead of the `foreColor` property.

**Example**

The following statement sets the variable `oldColor` to the foreground color of sprite 5:

-- Lingo syntax
oldColor = sprite(5).foreColor

// JavaScript syntax
var oldColor = sprite(5).foreColor;

The following statement makes 36 the number for the foreground color of a random sprite from sprites 11 to 13:

-- Lingo syntax
sprite(10 + random(3)).foreColor = 36

// JavaScript syntax
sprite(10 + random(3)).foreColor = 36;

**See also**

`backColor`, `color()`, `Sprite`

---

**frame**

**Usage**

-- Lingo syntax
_movie.frame

// JavaScript syntax
_movie.frame;

**Description**

Movie property; returns the number of the current frame of the movie. Read-only.

**Example**

This statement sends the playhead to the frame before the current frame:

-- Lingo syntax
_movie.go(_movie.frame - 1)
frameCount

Usage

-- Lingo syntax
memberObjRef.frameCount

// JavaScript syntax
memberObjRef.frameCount;

Description

Flash cast member property; indicates the number of frames in the Flash movie cast member. The frameCount member property can have integer values.

This property can be tested but not set.

Example

This sprite script displays, in the Message window, the channel number and the number of frames in a Flash movie:

-- Lingo syntax
property spriteNum

on beginSprite me
  put("The Flash movie in channel" && spriteNum && has" && sprite(spriteNum).member.frameCount && "frames."
end

// JavaScript syntax
function beginSprite() {
  trace("The Flash movie in channel " + (this.spriteNum) + " has " + sprite(this.spriteNum).member.frameCount + " frames.");
}

frameLabel

Usage

-- Lingo syntax
_movie.frameLabel

// JavaScript syntax
_movie.frameLabel;

Description

Movie property; identifies the label assigned to the current frame. Read/write during a Score recording session only.

When the current frame has no label, the value of the frameLabel property is 0.
Example

The following statement checks the label of the current frame. In this case, the current frameLabel value is Start:

-- Lingo syntax
put(_movie.frameLabel)

// JavaScript syntax
put(_movie.frameLabel);

See also
labelList, Movie

framePalette

Usage

-- Lingo syntax
_movie.framePalette

// JavaScript syntax
_movie.framePalette;

Description

Movie property; identifies the cast member number of the palette used in the current frame, which is either the current palette or the palette set in the current frame. Read/write during a Score recording session only.

When you want exact control over colors, use Shockwave Player.

Example

The following statement checks the palette used in the current frame. In this case, the palette is cast member 45.

-- Lingo syntax
put(_movie.framePalette)

// JavaScript syntax
put(_movie.framePalette);

This statement makes palette cast member 45 the palette for the current frame:

-- Lingo syntax
_movie.framePalette = 45

// JavaScript syntax
_movie.framePalette = 45;

See also
Movie
frameRate

Usage
-- Lingo syntax
memberObjRef.frameRate

// JavaScript syntax
memberObjRef.frameRate;

Description
Cast member property; specifies the playback frame rate for the specified digital video, or Flash movie cast member.

The possible values for the frame rate of a digital video member correspond to the radio buttons for selecting digital video playback options.

- When the frameRate member property is between 1 and 255, the digital video movie plays every frame at that frame rate. The frameRate member property cannot be greater than 255.
- When the frameRate member property is set to -1 or 0, the digital video movie plays every frame at its normal rate. This allows the video to sync to its soundtrack. When the frameRate is set to any value other than -1 or 0, the digital video soundtrack will not play.
- When the frameRate member property is set to -2, the digital video movie plays every frame as fast as possible.

For Flash movie cast members, the property indicates the frame rate of the movie created in Flash. This property can be tested but not set.

Example
This statement sets the frame rate of the QuickTime digital video cast member Rotating Chair to 30 frames per second:
-- Lingo syntax
member("Rotating Chair").frameRate = 30

// JavaScript syntax
member("Rotating Chair").frameRate = 30;

This statement instructs the QuickTime digital video cast member Rotating Chair to play every frame as fast as possible:
-- Lingo syntax
member("Rotating Chair").frameRate = -2

// JavaScript syntax
member("Rotating Chair").frameRate = -2;

The following sprite script checks to see if the sprite's cast member was originally created in Flash with a frame rate of less than 15 frames per second. If the movie's frame rate is slower than 15 frames per second, the script sets the playbackMode property for the sprite so it can be set to another rate. The script then sets the sprite's fixedRate property to 15 frames per second.
-- Lingo syntax
property spriteNum

on beginSprite me
    if sprite(spriteNum).member.frameRate < 15 then
        sprite(spriteNum).playBackMode = #fixed
        sprite(spriteNum).fixedRate = 15
    end if
end

// JavaScript syntax
function beginSprite () {
    var fr = sprite(this.spriteNum).member.frameRate;
    if (fr < 15) {
        sprite(this.spriteNum).playBackMode = symbol("fixed");
        sprite(this.spriteNum).fixedRate = 15;
    }
}

See also
fixedRate, playRate (QuickTime, AVI), currentTime (QuickTime, AVI),
playBackMode

frameRate (DVD)

Usage
-- Lingo syntax
dvdObjRef.frameRate

// JavaScript syntax
dvdObjRef.frameRate;

Description
DVD property. Returns the value of the DVD. Read-only.

The value is returned as one of the following floating-point numbers:

<table>
<thead>
<tr>
<th>Float</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0</td>
<td>The value could not be determined either because it is not in the title domain or because the title is not a one sequential video title.</td>
</tr>
<tr>
<td>25.0</td>
<td>The DVD is authored to play at 25 frames per second.</td>
</tr>
<tr>
<td>30.0</td>
<td>The DVD is authored to play at 30 frames per second.</td>
</tr>
<tr>
<td>29.97</td>
<td>The DVD is authored to play at 29.97 frames per second.</td>
</tr>
</tbody>
</table>

See also
DVD
frameScript

Usage

Lingo syntax
_movie.frameScript

JavaScript syntax
_movie.frameScript;

Description

Movie property; contains the unique cast member number of the frame script assigned to the current frame. Read/write during a Score recording session only.

During a Score generation session, you can also assign a frame script to the current frame by setting the frameScript property.

If there is no frame script assigned to the current frame, this property returns 0.

Example

The following statement displays the number of the script assigned to the current frame. In this case, the script number is 25.

Lingo syntax
put(_movie.frameScript)

JavaScript syntax
put(_movie.frameScript);

This statement makes the script cast member Button responses the frame script for the current frame:

Lingo syntax
_movie.frameScript = member("Button responses")

JavaScript syntax
_movie.frameScript = member("Button responses");

See also

Movie

frameSound1

Usage

Lingo syntax
_movie.frameSound1

JavaScript syntax
_movie.frameSound1;

Description

Movie property; determines the number of the cast member assigned to the first sound channel in the current frame. Read/write.

This property can also be set during a Score recording session.
Example
As part of a Score recording session, this statement assigns the sound cast member Jazz to the first sound channel:

-- Lingo syntax
_movie.frameSound1 = member("Jazz").number

// JavaScript syntax
_movie.frameSound1 = member("Jazz").number;

See also
frameSound2, Movie

frameSound2

Usage
-- Lingo syntax
_movie.frameSound2

// JavaScript syntax
_movie.frameSound2;

Description
Movie property; determines the number of the cast member assigned to the second sound channel in the current frame. Read/write.
This property can also be set during a Score recording session.

Example
As part of a Score recording session, this statement assigns the sound cast member Jazz to the second sound channel:

-- Lingo syntax
_movie.frameSound2 = member("Jazz").number

// JavaScript syntax
_movie.frameSound2 = member("Jazz").number;

See also
frameSound1, Movie

frameTempo

Usage
-- Lingo syntax
_movie.frameTempo

// JavaScript syntax
_movie.frameTempo;

Description
Movie property; indicates the tempo assigned to the current frame. Read/write during a Score recording session only.
Example
The following statement checks the tempo used in the current frame. In this case, the tempo is 15 frames per second.

--- Lingo syntax
put(_movie.frameTempo)

// JavaScript syntax
put(_movie.frameTempo);

See also
Movie, puppetTempo()

frameTransition

Usage

--- Lingo syntax
_movie.frameTransition

// JavaScript syntax
_movie.frameTransition;

Description
Movie property; specifies the number of the transition cast member assigned to the current frame. Read/write only during a Score recording session to specify transitions.

Example
When used in a Score recording session, this statement makes the cast member Fog the transition for the frame that Lingo is currently recording:

--- Lingo syntax
_movie.frameTransition = member("Fog")

// JavaScript syntax
_movie.frameTransition = member("Fog");

See also
Movie

front

Usage

member(whichCastmember).modelResource(whichModelResource).front

Description
3D #box model resource property; indicates whether the side of the box intersected by its -Z axis is sealed (TRUE) or open (FALSE).

The default value for this property is TRUE.
Example

This statement sets the `front` property of the model resource named `Crate` to FALSE, meaning the front of this box will be open:

```lingo
member("3D World").modelResource("Crate").front = FALSE
```

`back`, `bottom (3D)`, `top (3D)`, `left (3D)`, `right (3D)`

frontWindow

Usage

```lingo
-- Lingo syntax
_player.frontWindow

// JavaScript syntax
_player.frontWindow;
```

Description

Player property; indicates which movie in a window (MIAW) is currently frontmost on the screen. Read-only.

When the Stage is frontmost, `frontWindow` is the Stage. When a media editor or floating palette is frontmost, `frontWindow` returns VOID (Lingo) or null (JavaScript syntax).

Example

This statement determines whether the window "Music" is currently the frontmost window and, if it is, brings the window "Try This" to the front:

```lingo
if (_player.frontWindow = "Music") then
  window("Try This").moveToFront()
end if
```

```javascript
if (_player.frontWindow = "Music") {
  window("Try This").moveToFront();
}
```

See also

`Player`

fullScreen

Usage

```lingo
-- Lingo syntax
dvdObjRef.fullScreen

// JavaScript syntax
dvdObjRef.fullScreen;
```

Description

DVD property; specifies whether the DVD should play back in full screen mode. Pressing the escape key returns the display mode to non-fullscreen and sets the property to false. Currently unsupported on the Macintosh. Read/write.
See also

**getBoneID**

**Usage**

```idl
memberReference.modelResource.getBoneID("boneName")
```

**Description**

3D model resource property; returns the index number of the bone named `boneName` in the model resource. This property returns 0 if no bone by that name can be found.

**Example**

This statement returns an ID number for the bone ShinL:

```idl
put member("ParkScene").modelResource("LittleKid").getBoneId("ShinL")
```

```
-- 40
```

See also

**bone**

**globals**

**Usage**

```idl
the globals
```

**Description**

System property; this property contains a special property list of all current global variables with a value other than `VOID`. Each global variable is a property in the list, with the associated paired value.

You can use the following list operations on `globals`:

- `count()`—Returns the number of entries in the list.
- `getPropAt(n)`—Returns the name of the nth entry.
- `getProp(x)`—Returns the value of an entry with the specified name.
- `getAProp(x)`—Returns the value of an entry with the specified name.

**Note:** The `globals` property automatically contains the property `#version`, which is the version of Director running. This means there will always be at least one entry in the list, even if no global variables have been declared yet.

This property differs from `showGlobals` in that `the globals` can be used in contexts other than the Message window. To display `the globals` in the Message window, use `showGlobals`.

See also

```idl
showGlobals(), clearGlobals()
```
glossMap

Usage
member(whichCastmember).shader(whichShader).glossMap
member(whichCastmember).model(whichModel).shader.glossMap
member(whichCastmember).model(whichModel).shaderList[[index]].
glossMap

Description
3D #standard shader property; specifies the texture to use for gloss mapping.
When you set this property, the following properties are automatically set:
• The fourth texture layer of the shader is set to the texture you specified.
• The value of textureModeList[4] is set to #none.
• The value of blendFunctionList[4] is set to #multiply.

Example
This statement sets the texture named Oval as the glossMap value for the shader used by the
model named GlassBox:
member("3DPlanet").model("GlassBox").shader.glossMap = \
member("3DPlanet").texture("Oval")

See also
blendFunctionList, textureModeList, region, specularLightMap, diffuseLightMap

gravity

Usage
member(whichCastmember).modelResource(whichModelResource).gravity

Description
3D particle model resource property; when used with a model resource whose type is #particle,
allows you to get or set the gravity property of the resource as a vector.
This property defines the gravity force applied to all particles in each simulation step.
The default value for this property is vector(0,0,0).

Example
In this example, ThermoSystem is a model resource of the type #particle. This statement sets the
gravity property of ThermoSystem to the vector (0, -.1, 0), which pulls the particles of
thermoSystem gently down the y axis.
member("Fires").modelResource("ThermoSystem").gravity = \
vector(0, -.1, 0)

See also
drag, wind
gradientType

Usage

-- Lingo syntax
memberObjRef.gradientType

// JavaScript syntax
memberObjRef.gradientType;

Description

Vector shape cast member property; specifies the actual gradient used in the cast member’s fill.
Possible values are #linear or #radial. The gradientType is only valid when the fillMode is set to #gradient.
This property can be tested and set.

Example

This handler toggles between linear and radial gradients in cast member "backdrop":

-- Lingo syntax
on mouseUp me
  if member("backdrop").gradientType = #radial then
    member("backdrop").gradientType = #linear
  else
    member("backdrop").gradientType = #radial
  end if
end

// JavaScript syntax
function mouseUp() {
  var gt = member("backdrop").gradientType;
  if (gt = "radial") {
    member("backdrop").gradientType = symbol("linear");
  } else {
    member("backdrop").gradientType = symbol("radial");
  }
}

See also

fillMode

group

Usage

member(whichCastmember).group(whichGroup)
member(whichCastmember).group[index]

Description

3D element; a node in the 3D world that has a name, transform, parent, and children, but no other properties.
Every 3D cast member has a default group named World that cannot be deleted. The parent hierarchy of all models, lights, cameras, and groups that exist in the 3D world terminates in group("world").
Example

This statement shows that the fourth group of the cast member newAlien is the group Direct01:

```
put member("newAlien").group[4]
-- group("Direct01")
```

See also

newGroup, deleteGroup, child (3D), parent

height

Usage

```
-- Lingo syntax
imageObjRef.height
memberObjRef.height
spriteObjRef.height

// JavaScript syntax
imageObjRef.height;
memberObjRef.height;
spriteObjRef.height;
```

Description

Image, Member, and Sprite property; for vector shape, Flash, animated GIF, RealMedia, Windows Media, bitmap, and shape cast members, determines the height, in pixels, of the cast member displayed on the Stage. Read-only for cast members and image objects, read/write for sprites.

Example

This statement assigns the height of cast member Headline to the variable vHeight:

```
-- Lingo syntax
vHeight = member("Headline").height

// JavaScript syntax
var vHeight = member("Headline").height;
```

This statement sets the height of sprite 10 to 26 pixels:

```
-- Lingo syntax
sprite(10).height = 26

// JavaScript syntax
sprite(10).height = 26;
```

See also

Member, Sprite, width
height (3D)

Usage

member(whichCastmember).modelResource(whichModelResource).height
member(whichCastmember).texture(whichTexture).height

Description

3D #box model resource, #cylinder model resource, and texture property; indicates the height of the object.

The height of a #box or #cylinder model resource is measured in world units and can be tested and set. The default value for this property is 50.

The height of a texture is measured in pixels and can be tested but not set. The height of the texture is rounded from the height of the source of the texture to the nearest power of 2.

Example

This statement sets the height of the model resource named Tower to 225.0 world units:
member("3D World").modelResource("Tower").height = 225.0

This statement shows that the height of the texture named Marsmap is 512 pixels.
put member("scene").texture("Marsmap").height
  -- 512

See also

length (3D), width (3D)

heightVertices

Usage

member(whichCastmember).modelResource(whichModelResource).heightVertices

Description

3D #box model resource property; indicates the number of mesh vertices along the height of the box. Increasing this value increases the number of faces, and therefore the fineness, of the mesh.

The height of a box is measured along its Y axis.

Set the renderStyle property of a model's shader to #wire to see the faces of the mesh of the model's resource. Set the renderStyle property to #point to see just the vertices of the mesh.

The value of this property must be greater than or equal to 2. The default value is 4.

Example

The following statement sets the heightVertices property of the model resource named Tower to 10. Nine polygons will be used to define the geometry of the model resource along its Z axis; therefore, there will be ten vertices.
member("3D World").modelResource("Tower").heightVertices = 10

See also

height (3D)
highlightPercentage

Usage

member(whichCastmember).model(whichModel).toon.highlightPercentage
member(whichCastmember).model(whichModel).shader.highlightPercentage
member(whichCastmember).shader(whichShader).highlightPercentage

Description

3D toon modifier and #painter shader property; indicates the percentage of available colors that are used in the area of the model's surface where light creates highlights.

The range of this property is 0 to 100, and the default value is 50.

The number of colors used by the toon modifier and #painter shader for a model is determined by the colorSteps property of the model's toon modifier or #painter shader.

Example

The following statement sets the highlightPercentage property of the toon modifier for the model named Sphere to 50. Half of the colors available to the toon modifier for this model will be used for the highlight area of the model's surface.

member("shapes").model("Sphere").toon.highlightPercentage = 50

See also

highlightStrength, brightness

highlightStrength

Usage

member(whichCastmember).model(whichModel).toon.highlightStrength
member(whichCastmember).model(whichModel).shader.highlightStrength
member(whichCastmember).shader(whichShader).highlightStrength

Description

3D toon modifier and #painter shader property; indicates the brightness of the area of the model's surface where light creates highlights.

The default value of this property is 1.0.

Example

The following statement sets the highlightStrength property of the toon modifier for the model named Teapot to 0.5. The model's highlights will be moderately bright.

member("shapes").model("Teapot").toon.highlightStrength = 0.5

See also

highlightPercentage, brightness
**hilite**

**Usage**

```
-- Lingo syntax
memberObjRef.hilite

// JavaScript syntax
memberObjRef.hilite;
```

**Description**

Member property; determines whether a check box or radio button created with the button tool is selected (TRUE) or not (FALSE, default). Read/write.

**Example**

This statement checks whether the button named Sound on is selected and, if it is, turns sound channel 1 all the way up:

```
-- Lingo syntax
if (member("Sound On").hilite = TRUE) then
  sound(1).volume = 255
end if

// JavaScript syntax
if (member("Sound On").hilite == true) {
  sound(1).volume = 255;
}
```

This statement selects the button cast member powerSwitch by setting the hilite member property for the cast member to TRUE:

```
-- Lingo syntax
member("powerSwitch").hilite = TRUE

// JavaScript syntax
member("powerSwitch").hilite = true;
```

**See also**

Member

---

**hither**

**Usage**

```
member(whichCastmember).camera(whichCamera).hither
sprite(whichSprite).camera(index).hither
```

**Description**

3D camera property; indicates the distance in world units from the camera beyond which models are drawn. Objects closer to the camera than hither are not drawn.

The value of this property must be greater than or equal to 1.0 and has a default value of 5.0.

**Example**

The following statement sets the hither property of camera 1 to 1000. Models closer than 1000 world units from the camera will not be visible.

```
member("SolarSystem").camera[1].hither = 1000
```

**See also**

yon
hotSpot

Usage

-- Lingo syntax
memberObjRef.hotSpot

// JavaScript syntax
memberObjRef.hotSpot;

Description

Cursor cast member property; specifies the horizontal and vertical point location of the pixel that represents the hotspot within the animated color cursor cast member whichCursorCastMember. Director uses this point to track the cursor's position on the screen (for example, when it returns the values for the Lingo functions `mouseH` and `mouseV`) and to determine where a rollover (signaled by the Lingo message `mouseEnter`) occurs.

The upper left corner of a cursor is point(0,0), which is the default `hotSpot` value. Trying to set a point outside the bounds of the cursor produces an error. For example, setting the hotspot of a 16-by-16-pixel cursor to point(16,16) produces an error (because the starting point is 0,0, not 1,1).

This property can be tested and set.

Example

This handler sets the hotspot of a 32-by-32-pixel cursor (whose cast member number is stored in the variable `cursorNum`) to the middle of the cursor:

-- Lingo syntax
on startMovie
  member(cursorNum).hotSpot = point(16,16)
end

// JavaScript syntax
function startMovie() {
  member(cursorNum).hotSpot = point(16,16);
}

hotSpotEnterCallback

Usage

-- Lingo syntax
spriteObjRef.hotSpotEnterCallback

// JavaScript syntax
spriteObjRef.hotSpotEnterCallback;

Description

QuickTime VR sprite property; contains the name of the handler that runs when the cursor enters a QuickTime VR hot spot that is visible on the Stage. The QuickTime VR sprite receives the message first. The message has two arguments: the `me` parameter and the ID of the hot spot that the cursor entered.

To clear the callback, set this property to 0.

To avoid a performance penalty, set a callback property only when necessary.
This property can be tested and set.

See also
hotSpotExitCallback, nodeEnterCallback, nodeExitCallback, triggerCallback

**hotSpotExitCallback**

**Usage**

-- Lingo syntax
spriteObjRef.hotSpotExitCallback

// JavaScript syntax
spriteObjRef.hotSpotExitCallback;

**Description**

QuickTime VR sprite property; contains the name of the handler that runs when the cursor leaves a QuickTime VR hot spot that is visible on the Stage. The QuickTime VR sprite receives the message first. The message has two arguments: the `me` parameter and the ID of the hot spot that the cursor entered.

To clear the callback, set this property to 0.

To avoid a performance penalty, set a callback property only when necessary.

This property can be tested and set.

See also
hotSpotEnterCallback, nodeEnterCallback, nodeExitCallback, triggerCallback

**HTML**

**Usage**

-- Lingo syntax
memberObjRef.HTML

// JavaScript syntax
memberObjRef.HTML;

**Description**

Cast member property; accesses text and tags that control the layout of the text within an HTML-formatted text cast member.

This property can be tested and set.

**Example**

This statement displays in the message window the HTML formatting information embedded in the text cast member Home Page:

--Lingo syntax
put(member("Home Page").HTML)

// JavaScript syntax
trace(member("Home Page").HTML);

See also
importFileInto(), RTF
**hyperlink**

**Usage**

--- Lingo syntax
`chunkExpression hyperlink`

// JavaScript syntax
`chunkExpression hyperlink;`

**Description**

Text cast member property; returns the hyperlink string for the specified chunk expression in the text cast member.

This property can be both tested and set.

When retrieving this property, the link containing the first character of `chunkExpression` is used.

Hyperlinks may not overlap. Setting a hyperlink over an existing link, even partially over it), replaces the initial link with the new one.

Setting a hyperlink to an empty string removes it.

**Example**

The following handler creates a hyperlink in the first word of text cast member “MacroLink”. The text is linked to Macromedia's website.

--- Lingo syntax
```
on startMovie
    member("MacroLink").word[1].hyperlink = "http://www.macromedia.com"
end
```

// JavaScript syntax
```
function startMovie()
    member("MacroLink").getPropRef("word", 1).hyperlink = "http://www.macromedia.com";
}
```

**See also**

`hyperlinkRange`, `hyperlinkState`

**hyperlinkRange**

**Usage**

--- Lingo syntax
`chunkExpression hyperlinkRange`

// JavaScript syntax
`chunkExpression hyperlinkRange;`

**Description**

Text cast member property; returns the range of the hyperlink that contains the first character of the chunk expression.

This property can be tested but not set.
Like `hyperLink` and `hyperLinkState`, the returned range of the link contains the first character of `chunkExpression`.

See also

`hyperlink`, `hyperlinkState`

**hyperlinks**

**Usage**

-- Lingo syntax

```
chunkExpression.hyperlinks
```

// JavaScript syntax

```
chunkExpression.hyperlinks;
```

**Description**

Text cast member property; returns a linear list containing all the hyperlink ranges for the specified chunk of a text cast member. Each range is given as a linear list with two elements, one for the starting character of the link and one for the ending character.

**Example**

This statement returns all the links for the text cast member Glossary to the message window:

-- Lingo syntax

```
put(member("Glossary").hyperlinks) -- [[3, 8], [10, 16], [41, 54]]
```

// JavaScript syntax

```
trace(member("Glossary").hyperlinks); // [[3, 8], [10, 16], [41, 54]]
```

**hyperlinkState**

**Usage**

-- Lingo syntax

```
chunkExpression.hyperlinkState
```

// JavaScript syntax

```
chunkExpression.hyperlinkState;
```

**Description**

Text cast member property; contains the current state of the hyperlink. Possible values for the state are: `#normal`, `#active`, and `#visited`.

This property can be tested and set.

Like `hyperlink` and `hyperLinkRange`, the returned range of the link contains the first character of `chunkExpression`.
Example

The following handler checks to see if the hyperlink clicked is a web address. If it is, the state of
the hyperlink text state is set to #visited, and the movie branches to the web address.

```lingo
-- Lingo syntax
property spriteNum

on hyperlinkClicked me, data, range
    if data starts "http://" then
        currentMember = sprite(spriteNum).member
        currentMember.word[4].hyperlinkState = #visited
        gotoNetPage(data)
    end if
end

// JavaScript syntax
function hyperlinkClicked(data, range) {
    var st = data.slice(0,7);
    var ht = "http://";
    if (st = ht) {
        currentMember = sprite(spriteNum).member;
        currentMember.getPropRef("word", 4).hyperlinkState = symbol("visited");
        gotoNetPage(data);
    }
}
```

See also

hyperlink, hyperlinkRange

idleHandlerPeriod

Usage

```lingo
-- Lingo syntax
_movie.idleHandlerPeriod

// JavaScript syntax
_movie.idleHandlerPeriod;
```

Description

Movie property; determines the maximum number of ticks that passes until the movie sends an
idle message. Read/write.

The default value is 1, which tells the movie to send idle handler messages no more than 60
times per second.

When the playhead enters a frame, Director starts a timer, repaints the appropriate sprites on the
Stage, and issues an enterFrame event. Then, if the amount of time set for the tempo has elapsed,
Director generates an exitFrame event and goes to the next specified frame; if the amount of
time set for this frame hasn’t elapsed, Director waits until the time runs out and periodically
generates an idle message. The amount of time between idle events is determined by
idleHandlerPeriod.

Possible settings for idleHandlerPeriod are:

• 0—As many idle events as possible
• 1—Up to 60 per second
• 2—Up to 30 per second
• 3—Up to 20 per second
• $n$—Up to $60/n$ per second

The number of idle events per frame also depends on the frame rate of the movie and other activity, including whether scripts are executing. If the tempo is 60 frames per second (fps) and the idleHandlerPeriod value is 1, one idle event per frame occurs. If the tempo is 20 fps, three idle events per frame occur. Idle time results when Director doesn’t have a current task to perform and cannot generate any events.

In contrast, if the idleHandlerPeriod property is set to 0 and the tempo is very low, thousands of idle events can be generated.

The default value for this property is 1.

Example

The following statement causes the movie to send an idle message a maximum of once per second:

```
-- Lingo syntax
_movie.idleHandlerPeriod = 60

// JavaScript syntax
_movie.idleHandlerPeriod = 60;
```

See also

on idle, idleLoadMode, idleLoadPeriod, idleLoadTag, idleReadChunkSize, Movie

idleLoadMode

Usage

```
-- Lingo syntax
_movie.idleLoadMode

// JavaScript syntax
_movie.idleLoadMode;
```

Description

Movie property; determines when the `preload()` and `preLoadMember()` methods try to load cast members during idle periods. Read/write.

Idle periods can be one of the following values:

• 0—Does not perform idle loading
• 1—Performs idle loading when there is free time between frames
• 2—Performs idle loading during idle events
• 3—Performs idle loading as frequently as possible

The `idleLoadMode` property performs no function and works only in conjunction with the `preload()` and `preLoadMember()` methods.

Cast members that were loaded using idle loading remain compressed until the movie uses them. When the movie plays back, it may have noticeable pauses while it decompresses the cast members.
Example
This statement causes the movie to try as frequently as possible to load cast members designated for preloading by the `preLoad` and `preLoadMember` commands:

```plaintext
-- Lingo syntax
_movie.idleLoadMode = 3

// JavaScript syntax
_movie.idleLoadMode = 3;
```

See also
- `on idle`, `Movie`, `preLoad() (Movie)`, `preLoadMember()`

**idleLoadPeriod**

Usage

```plaintext
-- Lingo syntax
_movie.idleLoadPeriod

// JavaScript syntax
_movie.idleLoadPeriod;
```

Description
Movie property; determines the number of ticks that Director waits before trying to load cast members waiting to be loaded. Read/write.

The default value for `idleLoadPeriod` is 0, which instructs Director to service the load queue as frequently as possible.

Example
This statement instructs Director to try loading every 1/2 second (30 ticks) any cast members waiting to be loaded:

```plaintext
-- Lingo syntax
_movie.idleLoadPeriod = 30

// JavaScript syntax
_movie.idleLoadPeriod = 30;
```

See also
- `on idle`, `Movie`

**idleLoadTag**

Usage

```plaintext
-- Lingo syntax
_movie.idleLoadTag

// JavaScript syntax
_movie.idleLoadTag;
```

Description
Movie property; identifies or tags with a number the cast members that have been queued for loading when the computer is idle. Read/write.
The `idleLoadTag` property is a convenience that identifies the cast members in a group that you want to preload, and can be any number that you choose.

**Example**

This statement makes the number 10 the idle load tag:

---
Lingo syntax
_movie.idleLoadTag = 10
---
JavaScript syntax
_movie.idleLoadTag = 10;
See also
`on idle, Movie`

---

dieReadChunkSize

**Usage**

---
Lingo syntax
_movie.idleReadChunkSize
---
JavaScript syntax
_movie.idleReadChunkSize;

**Description**

Movie property; determines the maximum number of bytes that Director can load when it attempts to load cast members from the load queue. Read/write.

The default value of `idleReadChunkSize` is 32K.

**Example**

This statement specifies that 500K is the maximum number of bytes that Director can load in one attempt at loading cast members in the load queue:

---
Lingo syntax
_movie.idleReadChunkSize = (500 * 1024)
---
JavaScript syntax
_movie.idleReadChunkSize = (500 * 1024);
See also
`on idle, Movie`

---

**image (Image)**

**Usage**

---
Lingo syntax
imageObjRef.image
---
JavaScript syntax
imageObjRef.image;

**Description**

Image property. Refers to the image object of a bitmap or text cast member, of the Stage, or of a window. Read/write for a cast member’s image, read-only for an image of the Stage or a window.
Setting a cast member’s `image` property immediately changes the contents of the member. However, when getting the image of a member or window, Director creates a reference to the image of the specified member or window. If you make changes to the windows, the contents of the cast member or window change immediately.

If you plan to make a lot of changes to an item’s `image` property, it is faster to copy the item’s image property into a new image object using the `duplicate()` method, apply your changes to the new image object, and then set the original item’s image to the new image object. For nonbitmap members, it is always faster to use the `duplicate()` method.

**Example**

This statement puts the image of cast member `originalFlower` into cast member `newFlower`:

```lingo
member("newFlower").image = member("originalFlower").image
```

```javascript
member("newFlower").image = member("originalFlower").image;
```

These statements place a reference to the image of the stage into the variable `myImage` and then put that image into cast member `flower`:

```lingo
myImage = _movie.stage.image
member("flower").image = myImage
```

```javascript
var myImage = _movie.stage.image;
member("flower").image = myImage;
```

**See also**

`copyPixels()`, `draw()`, `duplicate()` (Image), `fill()`, `image()`, `setPixel()`

---

### image (RealMedia)

#### Usage

```lingo
memberOrSpriteObjRef.image
```

```javascript
memberOrSpriteObjRef.image;
```

#### Description

RealMedia sprite or cast member property; returns a Lingo image object containing the current frame of the RealMedia video stream. You can use this property to map RealVideo onto a 3D model (see the example below).

#### Example

This statement copies the current frame of the RealMedia cast member `Real` to the bitmap cast member `Still`:

```lingo
member("Still").image = member("Real").image
```

```javascript
member("Still").image = member("Real").image;
```
image (Window)

Usage

-- Lingo syntax
windowObjRef.image

// JavaScript syntax
windowObjRef.image;

Description

Window property; refers to the image object of a window. Read-only.

When you get the image of a window, Director creates a reference to the image of the specified
window. If you make changes to the image, the contents of the window change immediately.

If you plan to make a lot of changes to the image property, it is faster to copy the image property
into a new image object using the Member object's duplicate() method, apply your changes to
the new image object, and then set the original item's image to the new image object. For
nonbitmap members, it is always faster to use the duplicate() method.

Example

These statements place a reference to the image of the Stage into the variable myImage, and then
put that image into the window named Flower:

-- Lingo syntax
myImage = _movie.stage.image
window("Flower").image = myImage

// JavaScript syntax
var myImage = _movie.stage.image;
window("Flower").image = myImage;

See also

duplicate() (Member), Window

imageCompression

Usage

-- Lingo syntax
_movie.imageCompression
memberObjRef.imageCompression

// JavaScript syntax
_movie.imageCompression;
memberObjRef.imageCompression;

Description

Movie and bitmap cast member property; indicates the type of compression that Director applies
to internal (non-linked) bitmap cast members when saving a movie in Shockwave Player format.
Read/write.
Valid values for `imageCompression` include the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>#standard</td>
<td>Use the Director standard internal compression format.</td>
</tr>
<tr>
<td>#movieSetting</td>
<td>Use the compression settings of the movie, as stored in the <code>_movie.imageCompression</code> property. This is the default value for image formats not restricted to standard compression.</td>
</tr>
<tr>
<td>#jpeg</td>
<td>Use JPEG compression. See <code>imageQuality</code>.</td>
</tr>
</tbody>
</table>

You normally set this property in the Director Publish Settings dialog box.

**Example**

This statement displays in the Message window the `imageCompression` that applies to the currently playing movie:

```
-- Lingo syntax
put(_movie.imageCompression)

// JavaScript syntax
put(_movie.imageCompression);
```

**See also**

`imageQuality`, `Movie`

---

### imageEnabled

**Usage**

```
-- Lingo syntax
memberOrSpriteObjRef.imageEnabled

// JavaScript syntax
memberOrSpriteObjRef.imageEnabled;
```

**Description**

Cast member property and sprite property; controls whether a Flash movie or vector shape's graphics are visible (TRUE, default) or invisible (FALSE).

This property can be tested and set.

**Example**

This `beginSprite` script sets up a linked Flash movie sprite to hide its graphics when it first appears on the Stage and begins to stream into memory and saves its sprite number in a global variable called `gStreamingSprite` for use in a frame script later in the Score:

```
-- Lingo syntax
global gStreamingSprite

don beginSprite me
    gStreamingSprite = me.spriteNum
    sprite(gStreamingSprite).imageEnabled = FALSE
end

// JavaScript syntax
function beginSprite() {
    _global.gStreamingSprite = this.spriteNum;
    sprite(_global.gStreamingSprite).imageEnabled = 0;
}
```
In a later frame of the movie, this frame script checks to see if the Flash movie sprite specified by the global variable gStreamingSprite has finished streaming into memory. If it has not, the script keeps the playhead looping in the current frame until 100% of the movie has streamed into memory. It then sets the `imageEnabled` property to `TRUE` so that the graphics appear and lets the playhead continue to the next frame in the Score.

```lingo
-- Lingo syntax
global gStreamingSprite
on exitFrame me
    if sprite(gStreamingSprite).member.percentStreamed < 100 then
        _movie.go(_movie.frame)
    else
        sprite(gStreamingSprite).imageEnabled = TRUE
        _movie.updatestage()
    end if
end
```

```javascript
// JavaScript syntax
function exitFrame() {
    var stmSp = sprite(_global.gStreamingSprite).member.percentStreamed;
    if (stmSp < 100) {
        _movie.go(_movie.frame);
    } else {
        sprite(_global.gStreamingSprite).imageEnabled = 1;
        _movie.updatestage();
    }
}
```

### imageQuality

**Usage**

- Lingo syntax
  ```
  _movie.imageQuality
  memberObjRef.imageQuality
  ```

- JavaScript syntax
  ```
  _movie.imageQuality;
  memberObjRef.imageQuality;
  ```

**Description**

Movie and bitmap cast member property; indicates the level of compression to use when a movie’s `imageCompression` property is set to `#jpeg`. Read/write during authoring only.

The range of acceptable values is 0–100. Zero yields the lowest image quality and highest compression; 100 yields the highest image quality and lowest compression.

You can set this property only during authoring and it has no effect until the movie is saved in Shockwave Player format.

**Example**

This statement displays in the Message window the `imageQuality` that applies to the currently playing movie:

```lingo
-- Lingo syntax
put(_movie.imageQuality)
```

```javascript
// JavaScript syntax
put(_movie.imageQuality);
```

**See also**

`imageCompression`, `Movie`
immovable

**Usage**

```lingo
member(whichCastmember).model(whichModel).collision.immovable()
```

**Description**

3D collision modifier property; indicates whether a model can be moved as a result of collisions during animations. Specifying TRUE makes the model immovable; specifying FALSE allows the model to be moved. This property is useful as a way of improving performance during animation, because models that do not move do not need to be checked for collisions by Lingo.

This property has a default value of FALSE.

**Example**

This statement sets the immovable property of the collision modifier attached to the first model of the cast member named Scene to TRUE:

```lingo
member("Scene").model[1].collision.immovable = TRUE
```

**See also**

collision (modifier)

---

ink

**Usage**

```lingo```

```
// Lingo syntax
spriteObjRef.ink
```

```javascript```

```javascript
// JavaScript syntax
spriteObjRef.ink;
```

**Description**

Sprite property; determines the ink effect applied to a sprite. Read/write.

Valid values of `ink` are as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Copy</td>
</tr>
<tr>
<td>1</td>
<td>Transparent</td>
</tr>
<tr>
<td>2</td>
<td>Reverse</td>
</tr>
<tr>
<td>3</td>
<td>Ghost</td>
</tr>
<tr>
<td>4</td>
<td>Not copy</td>
</tr>
<tr>
<td>5</td>
<td>Not transparent</td>
</tr>
<tr>
<td>6</td>
<td>Not reverse</td>
</tr>
<tr>
<td>7</td>
<td>Not ghost</td>
</tr>
<tr>
<td>8</td>
<td>Matte</td>
</tr>
<tr>
<td>9</td>
<td>Mask</td>
</tr>
<tr>
<td>32</td>
<td>Blend</td>
</tr>
<tr>
<td>33</td>
<td>Add pin</td>
</tr>
<tr>
<td>34</td>
<td>Add</td>
</tr>
<tr>
<td>35</td>
<td>Subtract pin</td>
</tr>
<tr>
<td>36</td>
<td>Background transparent</td>
</tr>
<tr>
<td>37</td>
<td>Lightest</td>
</tr>
<tr>
<td>38</td>
<td>Subtract</td>
</tr>
<tr>
<td>39</td>
<td>Darkest</td>
</tr>
<tr>
<td>40</td>
<td>Lighten</td>
</tr>
<tr>
<td>41</td>
<td>Darken</td>
</tr>
</tbody>
</table>

---
In the case of 36 (background transparent), you select a sprite in the Score and select a transparency color from the background color box in the Tools window. You can also do this by setting the `backColor` property.

If you set this property within a script while the playhead is not moving, be sure to use the Movie object’s `updateStage()` method to redraw the Stage. If you change several sprite properties—or several sprites—use only one `updateStage()` method at the end of all the changes.

Example

This statement changes the variable `currentInk` to the value for the ink effect of sprite (3):

```-- Lingo syntax
currentInk = sprite(3).ink
```

```// JavaScript syntax
var currentInk = sprite(3).ink;
```

This statement gives sprite `(i + 1)` a matte ink effect by setting the ink effect of the sprite property to 8, which specifies matte ink:

```-- Lingo syntax
sprite(i + 1).ink = 8
```

```// JavaScript syntax
sprite(i + 1).ink = 8;
```

See also

`backColor`, `Sprite`, `updateStage()`

**inker (modifier)**

**Syntax**

```
member(whichCastmember).modelResource(whichModelResource).\ninker.inkerModifierProperty
```

```
modelResourceObjectReference.inker.inkerModifierProperty
```

**Description**

3D modifier; once you have added the `#inker` modifier to a model resource (using `addModifier`) you can get and set `#inker` modifier properties.

The `#inker` modifier adds silhouettes, creases, and boundary edges to an existing model; the `#inker` properties allow you to control the definition and emphasis of these properties.

When the `#inker` modifier is used in conjunction with the `#toon` modifier, the rendered effect is cumulative and varies depending on which modifier was first applied. The list of modifiers returned by the `modifier` property will list `#inker` or `#toon` (whichever was added first), but not both. The `#inker` modifier can not be used in conjunction with the `#sds` modifier.

The `#inker` modifier has the following properties:

- `lineColor` allows you to get or set the color of lines drawn by the inker.
- `silhouettes` allows you to get or set whether lines are drawn to define the edges along the border of a model, outlining its shape.
- `creases` allows you to get or set whether lines are drawn in creases.
- `creaseAngle` allows you to get or set the sensitivity of crease angle detection for the inker.
boundary allows you to get or set whether lines are drawn around the boundary of the surface.

lineOffset allows you to get or set where lines are drawn relative to the surface being shaded and the camera.

useLineOffset allows you to get or set whether lineOffset is on or off.

Note: For more detailed information about the following properties see the individual property entries.

See also
addModifier, modifiers, toon (modifier), shadowPercentage

**inlineImeEnabled**

Usage

-- Lingo syntax
_memberObjRef.inlineImeEnabled

// JavaScript syntax
_memberObjRef.inlineImeEnabled;

Description

Player property; determines whether the Director Inline IME feature is turned on. Read/write. When TRUE, this property allows the user to enter double-byte characters directly into the Director Text, Field, Script, and Message windows on Japanese systems.

The default value is determined by the Enable Inline IME setting in Director General Preferences.

See also
Player

**interval**

Usage

-- Lingo syntax
memberObjRef.interval

// JavaScript syntax
memberObjRef.interval;

Description

Cursor cast member property; specifies the interval, in milliseconds (ms), between each frame of the animated color cursor cast member whichCursorCastMember. The default interval is 100 ms.

The cursor interval is independent of the frame rate set for the movie using the tempo channel or the puppetTempo Lingo command.

This property can be tested and set.

Example

In this sprite script, when the animated color cursor stored in the cast member named Butterfly enters the sprite, the interval is set to 50 ms to speed up the animation. When the cursor leaves the sprite, the interval is reset to 100 ms to slow down the animation.
-- Lingo syntax
on mouseEnter
    member("Butterfly").interval = 50
end

on mouseLeave
    member("Butterfly").interval = 100
end

// JavaScript syntax
function mouseEnter()
    member("Butterfly").interval = 50;
}

function mouseLeave()
    member("Butterfly").interval = 100;
}

invertMask

Usage
-- Lingo syntax
memberObjRef.invertMask

// JavaScript syntax
memberObjRef.invertMask;

Description
QuickTime cast member property; determines whether Director draws QuickTime movies in the white pixels of the movie's mask (TRUE) or in the black pixels (FALSE, default).

This property can be tested and set.

Example
This handler reverses the current setting of the invertMask property of a QuickTime movie named Starburst:
-- Lingo syntax
on toggleMask
    member("Starburst").invertMask = not(member("Starburst").invertMask)
end

// JavaScript syntax
function toggleMask()
    member("Starburst").invertMask = !(member("Starburst").invertMask);
}

See also
    mask
isVRMovie

Usage

-- Lingo syntax
memberOrSpriteObjRef.isVRMovie

// JavaScript syntax
memberOrSpriteObjRef.isVRMovie;

Description

QuickTime cast member and sprite property; indicates whether a cast member or sprite is a
QuickTime VR movie that has not yet been downloaded (TRUE), or whether the cast member or
sprite isn't a QuickTime VR movie (FALSE).

Testing for this property in anything other than an asset whose type is #quickTimeMedia
produces an error message.

This property can be tested but not set.

Example

The following handler checks to see if the member of a sprite is a QuickTime movie. If it is, the
handler further checks to see if it is a QTVR movie. An alert is posted in any case.

-- Lingo syntax
on checkForVR(theSprite)
  if sprite(theSprite).member.type = #quickTimeMedia then
    if sprite(theSprite).isVRMovie then
      _player.alert("This is a QTVR asset.");
    else
      _player.alert("This is not a QTVR asset.");
    end if
  else
    _player.alert("This is not a QuickTime asset.");
  end if
end

// JavaScript syntax
function checkForVR(theSprite) {
  var memType = sprite(theSprite).member.type;
  if (memType = "quickTimeMedia") {
    var isType = sprite(theSprite).isVRMovie;
    if (isType = 1) {
      _player.alert("This is a QTVR asset.");
    } else {
      _player.alert("This is not a QTVR asset.");
    } else {
      _player.alert("This is not a QuickTime asset.");
    }
  }
}
**itemDelimiter**

**Usage**

the itemDelimiter

**Description**

Player property; indicates the special character used to separate items.

You can use the itemDelimiter to parse filenames by setting itemDelimiter to a backslash (\) in Windows or a colon (:) on the Macintosh. Restore the ItemDelimiter character to a comma (,) for normal operation.

This function can be tested and set.

**Example**

The following handler finds the last component in a Macintosh pathname. The handler first records the current delimiter and then changes the delimiter to a colon (:). When a colon is the delimiter, Lingo can use the last item of to determine the last item in the chunk that makes up a Macintosh pathname. Before exiting, the delimiter is reset to its original value.

```plaintext
on getLastComponent pathName
    save = the itemDelimiter
    the itemDelimiter = ":"
    f = the last item of pathName
    the itemDelimiter = save
    return f
end
```

**See also**

Player

**kerning**

**Usage**

-- Lingo syntax
memberObjRef.kerning

// JavaScript syntax
memberObjRef.kerning;

**Description**

Text cast member property; this property specifies whether the text is automatically kerned when the contents of the text cast member are changed.

When set to TRUE, kerning is automatic; when set to FALSE, kerning is not done.

This property defaults to TRUE.

**See also**

kerningThreshold
kerningThreshold

Usage

-- Lingo syntax
memberObjRef.kerningThreshold

// JavaScript syntax
memberObjRef.kerningThreshold;

Description

Text cast member property; this setting controls the size at which automatic kerning takes place in a text cast member. This has an effect only when the kerning property of the text cast member is set to TRUE.

The setting itself is an integer indicating the font point size at which kerning takes place.

This property defaults to 14 points.

See also

kerning

key

Usage

-- Lingo syntax
_key.key

// JavaScript syntax
_key.key;

Description

Key property; returns the value of the last key that was pressed. Read-only.

The returned value is the American National Standards Institute (ANSI) value that is assigned to the key, not the numerical value.

You can use key in handlers that perform certain actions when the user presses specific keys as shortcuts and other forms of interactivity. When used in a primary event handler, the actions you specify are the first to be executed.

Note: The value of key isn't updated if the user presses a key while Lingo or JavaScript syntax is in a loop.

Use the sample movie Keyboard Lingo to test which characters correspond to different keys on different keyboards.

Example

The following statements cause the movie to return to the main menu marker when the user presses the q key. Because the keyDownScript property is set to checkKey, the on prepareMovie handler makes the on checkKey handler the first event handler executed when a key is pressed. The on checkKey handler checks whether the q key is pressed and if it is, navigates to the main menu marker.
-- Lingo syntax
on prepareMovie
    keyDownScript = "checkKey"
end

on checkKey
    if (_key.key = "q") then _movie.go("Main Menu")
end if
end

// JavaScript syntax
function prepareMovie() {
    keyDownScript = checkKey();
}

function checkKey() {
    if (_key.key == "q") {
        _movie.go("Main Menu");
    }
}

This on keyDown handler checks whether the last key pressed is the z key and if it is, calls the on addNumbers handler:

-- Lingo syntax
on keyDown
    if (_key.key = "z") then addNumbers
end

// JavaScript syntax
function keyDown() {
    if (_key.key == "z") {
        addNumbers();
    }
}

See also
    commandDown, Key

keyboardFocusSprite

Usage
-- Lingo syntax
_movie.keyboardFocusSprite

// JavaScript syntax
_movie.keyboardFocusSprite;

Description
Movie property; lets the user set the focus for keyboard input (without controlling the cursor's insertion point) on a particular text sprite currently on the screen. Read/write.

This is the equivalent to using the Tab key when the autoTab property of the cast member is selected.

Setting keyboardFocusSprite to -1 returns keyboard focus control to the Score, and setting it to 0 disables keyboard entry into any editable sprite.

See also
    Movie
keyCode

Usage

-- Lingo syntax
_key.keyCode

// JavaScript syntax
_key.keyCode;

Description

Key property; returns the numerical code for the last key pressed. Read-only.

The returned value is the key's numerical value, not the American National Standards Institute (ANSI) value.

You can use keyCode to detect when the user has pressed an arrow or function key, which cannot be specified by the key property.

Use the sample movie Keyboard Lingo to test which characters correspond to different keys on different keyboards.

Example

This handler uses the Message window to display the appropriate key code each time a key is pressed:

-- Lingo syntax
on enterFrame
  keyDownScript = put(_key.keyCode)
end

// JavaScript syntax
function enterFrame() {
  keyDownScript = put(_key.keyCode);
}

This statement checks whether the up arrow (whose key code is 126) was pressed and if it was, goes to the previous marker:

-- Lingo syntax
if (_key.keyCode = 126) then
  _movie.goPrevious()
end if

// JavaScript syntax
if (_key.keyCode == 126) {
  _movie.goPrevious();
}

This handler checks whether one of the arrow keys was pressed and if one was, responds accordingly:

-- Lingo syntax
on keyDown
  case (_key.keyCode) of
    123: TurnLeft
    126: GoForward
    125: BackUp
    124: TurnRight
  end case

keyCode  811
end keyDown

// JavaScript syntax
function keyDown() {
  switch (_key.keyCode) {
  case 123: TurnLeft();
    break;
  case 126: GoForward();
    break;
  case 125: BackUp();
    break;
  case 124: TurnRight();
    break;
  }
}

See also
  Key, key

keyDownScript

Usage
  the keyDownScript

Description
  System property; specifies the Lingo that is executed when a key is pressed. The Lingo is written
  as a string, surrounded by quotation marks, and can be a simple statement or a calling script for
  a handler.

  When a key is pressed and the keyDownScript property is defined, Lingo executes the
  instructions specified for the keyDownScript property first. Unless the instructions include the
  pass command so that the keyDown message can be passed on to other objects in the movie, no
  other on keyDown handlers are executed.

  Setting the keyDownScript property performs the same function as using the when keyDown
  then command that appeared in earlier versions of Director.

  When the instructions you specify for the keyDownScript property are no longer appropriate,
  turn them off by using the statement set the keyDownScript to EMPTY.

Example
  The following statement sets keyDownScript to if the key = RETURN then go to the
  frame + 1. When this statement is in effect, the movie always goes to the next frame whenever
  the user presses the Return key.
  
  the keyDownScript = "if the key = RETURN then go to the frame + 1"

  The following statement sets keyDownScript to the custom handler myCustomHandler. A Lingo
  custom handler must be enclosed in quotation marks when used with the keyDownScript
  property.
  
  the keyDownScript = "myCustomHandler"

See also
  on keyDown, keyUpScript, mouseDownScript, mouseUpScript
keyframePlayer (modifier)

Syntax

member(whichCastmember).model(whichModel).\keyframePlayer.keyframePlayerModifierProperty

Description

3D modifier; manages the use of motions by models. The motions managed by the keyframePlayer modifier animate the entire model at once, unlike Bones player motions, which animate segments of the model called bones.

Motions and the models that use them must be created in a 3D modeling program, exported as W3D files, and then imported into a movie. Motions cannot be applied to model primitives created within Director.

Adding the keyframePlayer modifier to a model by using the addModifier command allows access to the following keyframePlayer modifier properties:

• playing indicates whether a model is executing a motion.
• playlist is a linear list of property lists containing the playback parameters of the motions that are queued for a model.
• currentTime indicates the local time, in milliseconds, of the currently playing or paused motion.
• playRate is a number that is multiplied by the scale parameter of the play() or queue() command to determine the playback speed of the motion.
• playlist.count returns the number of motions currently queued in the playlist.
• rootLock indicates whether the translational component of the motion is used or ignored.
• currentLoopState indicates whether the motion plays once or repeats continuously.
• blendTime indicates the length of the transition created by the modifier between motions when the modifier's autoBlend property is set to TRUE.
• autoBlend indicates whether the modifier creates a linear transition to the currently playing motion from the motion that preceded it.
• blendFactor indicates the degree of blending between motions when the modifier's autoBlend property is set to FALSE.
• lockTranslation indicates whether the model can be displaced from the specified planes.
• positionReset indicates whether the model returns to its starting position after the end of a motion or each iteration of a loop.
• rotationReset indicates the rotational element of a transition from one motion to the next, or the looping of a single motion.

Note: For more detailed information about these properties, see the individual property entries.

The keyframePlayer modifier uses the following commands:

• pause halts the motion currently being executed by the model.
• play() initiates or unpauses the execution of a motion.
• playNext() initiates playback of the next motion in the playlist.
• queue() adds a motion to the end of the playlist.
The `keyframePlayer` modifier generates the following events, which are used by handlers declared in the `registerForEvent()` and `registerScript()` commands. The call to the declared handler includes three arguments: the event type (either `#animationStarted` or `#animationEnded`), the name of the motion, and the current time of the motion. For detailed information about notification events, see the entry for `registerForEvent()`.

`#animationStarted` is sent when a motion begins playing. If blending is used between motions, the event is sent when the transition begins.

`#animationEnded` is sent when a motion ends. If blending is used between motions, the event is sent when the transition ends.

See also

- `addModifier`, `modifiers`, `bonesPlayer (modifier)`, `motion`

### keyUpScript

**Usage**

the `keyUpScript`

**Description**

System property; specifies the Lingo that is executed when a key is released. The Lingo is written as a string, surrounded by quotation marks, and can be a simple statement or a calling script for a handler.

When a key is released and the `keyUpScript` property is defined, Lingo executes the instructions specified for the `keyUpScript` property first. Unless the instructions include the `pass` command so that the `keyUp` message can be passed on to other objects in the movie, no other `on keyUp` handlers are executed.

When the instructions you've specified for the `keyUpScript` property are no longer appropriate, turn them off by using the statement `set the `keyUpScript` to empty`.

**Example**

The following statement sets `keyUpScript` to `if the key = RETURN then go to the frame + 1`. When this statement is in effect, the movie always goes to the next frame whenever the user presses the Return key.

```lingo
the `keyUpScript` = "if the key = RETURN then go to the frame + 1"
```

The following statement sets `keyUpScript` to the custom handler `myCustomHandler`. A Lingo custom handler must be enclosed in quotation marks when used with the `keyUpScript` property.

```lingo
the `keyUpScript` = "myCustomHandler"
```

See also

- `on keyUp`
**labelList**

**Usage**

the labelList

**Description**

System property; lists the frame labels in the current movie as a Return-delimited string (not a list) containing one label per line. Labels are listed according to their order in the Score. (Because the entries are Return-delimited, the end of the string is an empty line after the last Return. Be sure to remove this empty line if necessary.)

**Example**

This statement makes a list of frame labels in the content of the field cast member Key Frames:

This handler determines the label that starts the current scene:

**See also**

frameLabel, label(), marker()

---

**lastChannel**

**Usage**

-- Lingo syntax
_movie.lastChannel

// JavaScript syntax
_movie.lastChannel;

**Description**

Movie property; the number of the last channel in the movie, as entered in the Movie Properties dialog box. Read-only.

To see an example of `lastChannel` used in a completed movie, see the QT and Flash movie in the Learning/Lingo Examples folder inside the Director application folder.

**Example**

This statement displays the number of the last channel of the movie in the Message window:

-- Lingo syntax
put(_movie.lastChannel)

// JavaScript syntax
put(_movie.lastChannel);

**See also**

Movie
lastClick

Usage
-- Lingo syntax
_player.lastClick

// JavaScript syntax
_player.lastClick;

Description
Player property; returns the time in ticks (1 tick = 1/60 of a second) since the mouse button was last pressed. Read-only.

Example
This statement checks whether 10 seconds have passed since the last mouse click and, if so, sends the playhead to the marker No Click:

-- Lingo syntax
if (_player.lastClick > (10 * 60)) then
    _movie.go("No Click")
end if

// JavaScript syntax
if (_player.lastClick > (10 * 60)) {
    _movie.go("No Click");
}

See also
lastEvent, lastKey, lastRoll, Player

lastError

Usage
-- Lingo syntax
memberOrSpriteObjRef.lastError

// JavaScript syntax
memberOrSpriteObjRef.lastError;

Description
RealMedia sprite or cast member property; allows you to get the last error symbol returned by RealPlayer as a Lingo symbol. The error symbols returned by RealPlayer are strings of simple English and provide a starting point for the troubleshooting process. This property is dynamic during playback and can be tested but not set.

The value #PNR_OK indicates that everything is functioning properly.
Example
The following examples show that the last error returned by RealPlayer for the sprite 2 and the cast member Real was #PNR_OUTOFMEMORY:

-- Lingo syntax
put(sprite(2).lastError) -- #PNR_OUTOFMEMORY
put(member("Real").lastError) -- #PNR_OUTOFMEMORY

// JavaScript syntax
trace(sprite(2).lastError); // #PNR_OUTOFMEMORY
put(member("Real").lastError); // #PNR_OUTOFMEMORY

lastEvent

Usage
-- Lingo syntax
_player.lastEvent

// JavaScript syntax
_player.lastEvent;

Description
Player property; returns the time in ticks (1 tick = 1/60 of a second) since the last mouse click, rollover, or key press occurred. Read-only.

Example
This statement checks whether 10 seconds have passed since the last mouse click, rollover, or key press and, if so, sends the playhead to the marker Help:

-- Lingo syntax
if (_player.lastEvent > (10 * 60)) then
    _movie.go("Help")
end if

// JavaScript syntax
if (_player.lastEvent > (10 * 60)) {
    _movie.go("Help");
}

See also
lastClick, lastKey, lastRoll, Player

lastFrame

Usage
-- Lingo syntax
_movie.lastFrame

// JavaScript syntax
_movie.lastFrame;

Description
Movie property; displays the number of the last frame in the movie. Read-only.
Example

This statement displays the number of the last frame of the movie in the Message window:

```plaintext
-- Lingo syntax
put(_movie.lastFrame)

// JavaScript syntax
put(_movie.lastFrame);
```

See also

Movie

lastKey

Usage

```plaintext
-- Lingo syntax
_player.lastKey

// JavaScript syntax
_player.lastKey;
```

Description

Player property; gives the time in ticks (1 tick = 1/60 of a second) since the last key was pressed. Read-only.

Example

This statement checks whether 10 seconds have passed since the last key was pressed and, if so, sends the playhead to the marker No Key:

```plaintext
-- Lingo syntax
if (_player.lastKey > (10 * 60)) then
_movie.go("No Key")
end if

// JavaScript syntax
if (_player.lastKey > (10 * 60)) {
_movie.go("No Key");
}
```

See also

lastClick, lastEvent, lastRoll, Player

lastRoll

Usage

```plaintext
-- Lingo syntax
_player.lastRoll

// JavaScript syntax
_player.lastRoll;
```

Description

Player property; gives the time in ticks (1 tick = 1/60 of a second) since the mouse was last moved. Read-only.
Example

This statement checks whether 45 seconds have passed since the mouse was last moved and, if so, sends the playhead to the marker Attract Loop:

-- Lingo syntax
if (_player.lastRoll > (45 * 60)) then
    _movie.go("Attract Loop")
end if

// JavaScript syntax
if (_player.lastRoll > (45 * 60)) {
    _movie.go("Attract Loop");
}

See also

lastClick, lastEvent, lastKey, Player

left

Usage

-- Lingo syntax
spriteObjRef.left

// JavaScript syntax
spriteObjRef.left;

Description

Sprite property; identifies the left horizontal coordinate of the bounding rectangle of a sprite. Read/write.

Sprite coordinates are measured in pixels, starting with (0,0) at the upper left corner of the Stage.

Example

The following statement determines whether the sprite's left edge is to the left of the Stage's left edge. If the sprite's left edge is to the Stage's left edge, the script runs the handler offLeftEdge:

-- Lingo syntax
if (sprite(3).left < 0) then
    offLeftEdge()
end if

// JavaScript syntax
if (sprite(3).left < 0) {
    offLeftEdge();
}

This statement measures the left horizontal coordinate of the sprite numbered (i + 1) and assigns the value to the variable named vLowest:

-- Lingo syntax
vLowest = sprite(i + 1).left

// JavaScript syntax
var vLowest = sprite(i + 1).left

See also

bottom, height, locH, locV, right, Sprite, top, width
left (3D)

Usage

\[
\text{member(}\text{whichCastmember} \text{).modelResource(}\text{whichModelResource} \text{).left}
\]

Description

3D \#box model resource property; indicates whether the side of the box intersected by its -X axis is sealed (TRUE) or open (FALSE).

The default value for this property is TRUE.

Example

This statement sets the left property of the model resource named Crate to FALSE, meaning the left side of this box will be open:

\[
\text{member(}\text{"3D World"} \text{).modelResource(}\text{"crate"} \text{).left = FALSE}
\]

See also

back, front, bottom (3D), top (3D), right (3D)

leftIndent

Usage

\[
\text{chunkExpression.leftIndent}
\]

Description

Text cast member property; contains the number of pixels the left margin of chunkExpression is offset from the left side of the text cast member.

The value is an integer greater than or equal to 0.

This property can be tested and set.

Example

This line indents the first line of text cast member “theStory” by ten pixels:

\[
\text{member(}\text{"theStory"} \text{).line[}1\text{].leftIndent = 10}
\]

See also

firstIndent, rightIndent

length (3D)

Usage

\[
\text{member(}\text{whichCastmember} \text{).modelResource(}\text{whichModelResource} \text{).length}
\]

Description

3D \#box model resource, \#plane model resource, and vector property; indicates the length in world units of the box or plane.

The length of a box is measured along its Z axis. The default length of a box is 50.

The length of a plane is measured along its Y axis. The default length of a plane is 1.
The length of a vector is its distance in world units from \texttt{vector(0, 0, 0)}. This is the same as the magnitude of the vector.

**Example**

This statement sets the variable \texttt{myBoxLength} to the length of the model resource named \texttt{GiftBox}.

\begin{verbatim}
myBoxLength = member("3D World").modelResource("GiftBox").length
\end{verbatim}

**See also**

\texttt{height (3D), width (3D), magnitude}

**lengthVertices**

**Usage**

\begin{verbatim}
member(whichCastmember).modelResource(whichModelResource).\lengthVertices
\end{verbatim}

**Description**

3D \texttt{#box} and \texttt{#plane} model resource property; indicates the number of mesh vertices along the length of the box or plane. Increasing this value increases the number of faces, and therefore the fineness, of the mesh.

The length of a box is measured along its Z axis. The length of a plane is measured along its Y axis.

Set the \texttt{renderStyle} property of a model's shader to \texttt{#wire} to see the faces of the mesh of the model's resource. Set the \texttt{renderStyle} property to \texttt{#point} to see just the vertices of the mesh.

The value of this property must be greater than or equal to 2. The default value is 4.

**Example**

The following statement sets the \texttt{lengthVertices} property of the model resource named Tower to 10. Nine triangles will be used to define the geometry of the model resource along its Y axis; therefore, there will be ten vertices.

\begin{verbatim}
member("3D World").modelResource("Tower").lengthVertices = 10
\end{verbatim}

**See also**

\texttt{length (3D)}

**level**

**Usage**

\begin{verbatim}
member(whichCastmember).model(whichModel).lod.level
\end{verbatim}

**Description**

3D \texttt{lod} modifier property; indicates the amount of detail removed by the modifier when its \texttt{auto} property is set to \texttt{FALSE}. The range of this property is 0.0 to 100.00.

When the modifier's \texttt{auto} property is set to \texttt{TRUE}, the value of the \texttt{level} property is dynamically updated, but cannot be set.
The #lod modifier can only be added to models created outside of Director in 3D modeling programs. The value of the type property of the model resources used by these models is #fromFile. The modifier cannot be added to primitives created within Director.

Example

The following statement sets the level property of the lod modifier of the model Spaceship to 50. If the lod modifier's auto property is set to FALSE, Spaceship will be drawn at a medium level of detail. If the lod modifier's auto property is set to TRUE, this code will have no effect.

member("3D World").model("Spaceship").lod.level = 50

See also

lod (modifier), auto, bias

lifetime

Usage

member(whichCastmember).modelResource(modelResource).lifetime

Description

3D #particle model resource property; for all particles in a particle system, this property indicates the number of milliseconds from the creation of a particle to the end of its existence. The default value of this property is 10,000.

Example

In this example, ThermoSystem is a model resource of the type #particle. This statement sets the lifetime property of ThermoSystem to 90.0. This means each particle of ThermoSystem will exist for 90 milliseconds.

member(8,2).modelResource("ThermoSystem").lifetime = 90.0

See also

emitter

light

Usage

member(whichCastmember).light(whichLight)
member(whichCastmember).light[index]
member(whichCastmember).light[whichLight].whichLightProperty
member(whichCastmember).light[index].whichLightProperty

Description

3D element; an object at a vector position from which light emanates.

Example

This example shows the two ways of referring to a light. The first line uses a string in parentheses and the second line uses the a number in brackets. The string is the light's name and the number is the position of the light in the cast member's list of lights.

thisLight = member("3D World").light("spot01")
thisLight = member("3D World").light[2]
See also
   newLight, deleteLight

**lineColor**

**Usage**

```lingo
member(whichCastmember).model(whichModel).inker.lineColor
member(whichCastmember).model(whichModel).toon.lineColor
```

**Description**

3D toon and inker modifier property; indicates the color of the lines drawn on the model by the modifier. For this property to have an effect, either the modifier's creases, silhouettes, or boundary property must be set to TRUE.

The default value for this property is rgb(0, 0, 0).

**Example**

This statement sets the color of all lines drawn by the toon modifier on the model named Teapot to rgb(255, 0, 0), which is red:

```lingo
member("shapes").model("Teapot").toon.lineColor = rgb(255, 0, 0)
```

See also
   creases, silhouettes, boundary, lineOffset

**lineCount**

**Usage**

```lingo
-- Lingo syntax
memberObjRef.lineCount
```

// JavaScript syntax
```
memberObjRef.lineCount;
```

**Description**

Cast member property; indicates the number of lines that appear in the field cast member on the Stage according to the way the string wraps, not the number of carriage returns in the string.

**Example**

This statement determines how many lines the field cast member Today's News has when it appears on the Stage and assigns the value to the variable `numberOfLines`:

```lingo
-- Lingo syntax
numberOfLines = member("Today's News").lineCount
```

// JavaScript syntax
```
var numberOfLines = member("Today's News").lineCount;
```
lineDirection

Usage

member(whichCastMember).lineDirection

Description

Shape member property; this property contains a 0 or 1 indicating the slope of the line drawn.
If the line is inclined from left to right, the property is set to 1; and if it is declined from left to right, the property is set to 0.
This property can be tested and set.

Example

This handler toggles the slope of the line in cast member "theLine", producing a see-saw effect:

```javascript
on seeSaw
  member("theLine").lineDirection = \n  not member("theLine").lineDirection
end
```

lineHeight

Usage

member(whichCastMember).lineHeight

the lineHeight of member whichCastMember

Description

Cast member property; determines the line spacing used to display the specified field cast member. The parameter `whichCastMember` can be either a cast member name or number.

Setting the `lineHeight` member property temporarily overrides the system’s setting until the movie closes. To use the desired line spacing throughout a movie, set the `lineHeight` member property in an `on prepareMovie` handler.

This property can be tested and set.

Example

This statement sets the variable `oldHeight` to the current `lineHeight` setting for the field cast member Rokujo Speaks:

```javascript
oldHeight = member("Rokujo Speaks").lineHeight
```

See also

text, alignment, font, fontSize, fontStyle
**lineOffset**

**Usage**

```lingo
member(whichCastmember).model(whichModel).toon.lineOffset
member(whichCastmember).model(whichModel).inker.lineOffset
```

**Description**

3D toon and inker modifier property; indicates the apparent distance from the model's surface at which lines are drawn by the modifier. For this property to have an effect, the modifier's useLineOffset property must be set to TRUE, and one or more of its creases, silhouettes, or boundary properties must also be set to TRUE.

This range of this property is -100.00 to +100.00. Its default setting is -2.0.

**Example**

The following statement sets the lineOffset property of the toon modifier for the model named Teapot to 10. The lines drawn by the toon modifier on the surface of the model will stand out more than they would at the default setting of -2.

```lingo
member("shapes").model("Teapot").toon.lineOffset = 10
```

**See also**

creases, silhouettes, boundary, useLineOffset, lineColor

**lineSize**

**Usage**

```lingo
member(whichCastMember).lineSize
the lineSize of member whichCastMember
sprite whichSprite.lineSize
the lineSize of sprite whichSprite
```

**Description**

Shape cast member property; determines the thickness, in pixels, of the border of the specified shape cast member displayed on the Stage. For nonrectangular shapes, the border is the edge of the shape, not its bounding rectangle.

The lineSize setting of the sprite takes precedence over the lineSize setting of the member. If Lingo changes the member's lineSize setting while a sprite is on the Stage, the sprite's lineSize setting remains in effect until the sprite is finished.

For the value set by Lingo to last beyond the current sprite, the sprite must be a scripted sprite. This property can be tested and set.

**Example**

This statement sets the thickness of the shape cast member Answer Box to 5 pixels:

```lingo
member("Answer Box").lineSize = 5
```

This statement displays the thickness of the border of sprite 4:

```lingo
thickness = sprite(4).lineSize
```

This statement sets the thickness of the border of sprite 4 to 3 pixels:

```lingo
sprite(4).lineSize = 3
```
linked

Usage

-- Lingo syntax
memberObjRef.linked

// JavaScript syntax
memberObjRef.linked;

Description

Member property; controls whether a script, Flash movie, or animated GIF file is stored in an external file (TRUE, default), or inside the Director cast library (FALSE). Read/write for script, Flash, and animated GIF members, read-only for all other member types.

When the data is stored externally in a linked file, the cast member's pathName property must point to the location where the movie file can be found.

Example

This statement converts Flash cast member "homeBodies" from a linked member to an internally stored member.

-- Lingo syntax
member("homeBodies").linked = 0

// JavaScript syntax
member("homeBodies").linked = 0;

See also

Member

loaded

Usage

-- Lingo syntax
memberObjRef.loaded

// JavaScript syntax
memberObjRef.loaded;

Description

Member property; specifies whether a specified cast member is loaded into memory (TRUE) or not (FALSE). Read-only.

Different cast member types have slightly different behaviors for loading:

• Shape and script cast members are always loaded into memory.
• Movie cast members are never unloaded.
• Digital video cast members can be preloaded and unloaded independent of whether they are being used. (A digital video cast member plays faster from memory than from disk.)
Example

This statement checks whether cast member Demo Movie is loaded in memory and if it isn't, goes to an alternative movie:

-- Lingo syntax
if member("Demo Movie").loaded = FALSE then
    _movie.go(1, "Waiting.dir")
end if

// JavaScript syntax
if (member("Demo Movie").loaded == false) {
    _movie.go(1, "Waiting.dir")
}

See also
Member

loc (backdrop and overlay)

Usage
sprite(whichSprite).camera(index).backdrop[index].loc
member(whichCastmember).camera(whichCamera).backdrop[index].loc
sprite(whichSprite).camera(index).overlay[index].loc
member(whichCastmember).camera(whichCamera).overlay[index].loc

Description
3D backdrop and overlay property; indicates the 2D location of the backdrop or overlay, as measured from the upper left corner of the sprite.

This property is initially set as a parameter of the addBackdrop, addOverlay, insertBackdrop, or insertOverlay command which creates the backdrop or overlay.

Example

This statement positions the first backdrop of the camera of sprite 2:
sprite(2).camera.backdrop[1].loc = point(120, 120)

See also
bevelDepth, overlay, regPoint (3D)

locH

Usage
-- Lingo syntax
spriteObjRef.locH

// JavaScript syntax
spriteObjRef.locH;

Description
Sprite property; indicates the horizontal position of a sprite’s registration point. Read/write.
Sprite coordinates are relative to the upper left corner of the Stage.
To make the value last beyond the current sprite, make the sprite a scripted sprite.
Example

This statement puts sprite 15 at the same horizontal location as the mouse click:

-- Lingo syntax
sprite(15).locH = _mouse.mouseH

// JavaScript syntax
sprite(15).locH = _mouse.mouseH;

See also
bottom, height, left, locV, point(), right, Sprite, top, updateStage()

lockTranslation

Usage

member(whichCastmember).model(whichModel).bonesPlayer.
lockTranslation
member(whichCastmember).model(whichModel).keyframePlayer.
lockTranslation

Description

3D #bonesPlayer and #keyframePlayer modifier property; prevents displacement from the specified plane(s) except by the absolute translation of the motion data. Any additional translation introduced either manually or through cumulative error is removed. The possible values of #none, #x, #y, #z, #xy, #yz, #xz, and #all control which of the three translational components are controlled for each frame. When a lock on an axis is turned on, the current displacement along that axis is stored and used thereafter as the fixed displacement to which the animation is relative. This displacement can be reset by deactivating that axis lock, moving the object, and reactivating that axis lock.

In other words, it defines the axis of translation to ignore when playing back a motion. To keep a model locked to a ground plane with the top pointing along the z-axis, set lockTranslation to #z. The default value for this property is #none.

Example

This statement sets the lockTranslation property of the model named Walker to #z.

member("ParkScene").model("Walker").bonesPlayer.
lockTranslation = #z

See also
immovable

locV

Usage

-- Lingo syntax
spriteObjRef.locV

// JavaScript syntax
spriteObjRef.locV;

Description

Sprite property; indicates the vertical position of a sprite's registration point. Read/write.
Sprite coordinates are relative to the upper left corner of the Stage.
To make the value last beyond the current sprite, make the sprite a scripted sprite.

Example
This statement puts sprite 15 at the same vertical location as the mouse click:

-- Lingo syntax
sprite(15).locV = _mouse.mouseV

// JavaScript syntax
sprite(15).locV = _mouse.mouseV;

See also
bottom, height, left, locH, point(), right, Sprite, top, updateStage()

locZ

Usage

-- Lingo syntax
spriteObjRef.locZ

// JavaScript syntax
spriteObjRef.locZ;

Description
Sprite property; specifies the dynamic Z-order of a sprite, to control layering without having to manipulate sprite channels and properties. Read/write.

This property can have an integer value from negative 2 billion to positive 2 billion. Larger numbers cause the sprite to appear in front of sprites with smaller numbers. If two sprites have the same locZ value, the channel number then takes precedence for deciding the final display order of those two sprites. This means sprites in lower numbered channels appear behind sprites in higher numbered channels even when the locZ values are equal.

By default, each sprite has a locZ value equal to its own channel number.

Layer-dependent operations such as hit detection and mouse events obey sprites’ locZ values, so changing a sprite’s locZ value can make the sprite partially or completely obscured by other sprites and the user may be unable to click on the sprite.

Other Director functions do not follow the locZ ordering of sprites. Generated events still begin with channel 1 and increase consecutively from there, regardless of the sprite’s Z-order.

Example
This handler uses a global variable called gHighestSprite which has been initialized in the startMovie handler to the number of sprites used. When the sprite is clicked, its locZ is set to gHighestSprite + 1, which moves the sprite to the foreground on the stage. Then gHighestSprite is incremented by 1 to prepare for the next mouseUp call.

-- Lingo syntax
on mouseUp me
  global gHighestSprite
  sprite(me.spriteNum).locZ = gHighestSprite + 1
  gHighestSprite = gHighestSprite + 1
end
// JavaScript syntax
function mouseUp() {
    _global.gHighestSprite;
    sprite(this.spriteNum).locZ = _global.gHighestSprite + 1
    _global.gHighestSprite = _global.gHighestSprite + 1
}

See also
locH, locV, Sprite

lod (modifier)

Usage
member(whichCastmember).model(whichModel).lod.lodModifierProperty

Description
3D modifier; dynamically removes detail from models as they move away from the camera.

This modifier can only be added to models created outside of Director in 3D modeling programs. The value of the type property of the model resources used by these models is #fromFile. All such models use detail reduction whether or not the lod modifier is attached. Attaching the modifier allows you to control the properties of detail reduction. The modifier cannot be added to primitives created within Director.

The lod modifier data is generated by 3D modeling programs for all models. Setting the userData property "sw3d_no_lod = true" allows you to specify that the lod modifier data and memory be released when streaming is complete.

Be careful when using the sds and lod modifiers together, because they perform opposite functions (the sds modifier adds geometric detail and the lod modifier removes geometric detail). Before adding the sds modifier, it is recommended that you disable the lod.auto modifier property and set the lod.level modifier property to maximum resolution, as follows:

member("myMember").model("myModel").lod.auto = 0
member("myMember").model("myModel").lod.level = 100
member("myMember").model("myModel").addmodifier(#sds)

The lod modifier has the following properties:

- auto allows the modifier to set the level of detail reduction as the distance between the model and the camera changes. The value of the modifier's level property is updated, but setting the level property will have no effect when the auto property is set to TRUE.
- bias indicates how aggressively the modifier removes detail from the model when the modifier's auto property is set to TRUE. The range for this property is from 0.0 (removes all polygons) to 100.0 (removes no polygons). The default setting for this property is 100.0.
- level indicates the amount of detail reduction there will be when the modifier's auto property is set to FALSE. The range of this property is 0.0 to 100.00.

Note: For more detailed information about these properties, see the individual property entries.

See also
sds (modifier), auto, bias, level, addModifier
**loop (3D)**

**Usage**

```
member(whichCastmember).loop
```

**Description**

3D cast member property; indicates whether motions applied to the first model in the cast member repeat continuously (TRUE) or play once and stop (FALSE).

The default setting for this property is TRUE.

**Example**

This statement sets the loop property of the cast member named Walkers to TRUE. Motions being executed by the first model in Walker will repeat continuously.

```
member("Walkers").loop = TRUE
```

**See also**

`motion`, `play()` (3D), `queue()` (3D), `animationEnabled`

---

**loop (emitter)**

**Usage**

```
member(whichCastmember).modelResource(whichModelResource).\emitter.loop
```

**Description**

3D property; when used with a model resource whose type is `#particle`, this property allows you to both get and set what happens to particles at the end of their lifetime. A loop value of TRUE causes particles to be reborn at the end of their lifetime at the emitter location defined by the emitter's `region` property. A value of FALSE causes the particles to die at the end of their lifetime. The default setting for this property is TRUE.

**Example**

In this example, ThermoSystem is a model resource of the type `#particle`. This statement sets the emitter.loop property of ThermoSystem to 1, which causes the particles of ThermoSystem to be continuously emitted.

```
member("Fires").modelResource("ThermoSystem").emitter.loop = 1
```

**See also**

`emitter`
loop (Member)

Usage

-- Lingo syntax
memberObjRef.loop

// JavaScript syntax
memberObjRef.loop;

Description

Cast member property; determines whether the specified digital video, sound, or Flash movie cast member is set to loop (TRUE) or not (FALSE).

Example

This statement sets the QuickTime movie cast member Demo to loop:

-- Lingo syntax
member("Demo").loop = 1

// JavaScript syntax
member("Demo").loop = 1;

loop (Flash)

Usage

sprite(whichFlashSprite).loop
the loop of sprite whichFlashSprite
member (whichFlashMember).loop
the loop of member whichFlashMember

Description

Flash sprite and member property; controls whether a Flash movie plays in a continuous loop (TRUE) or plays once and then stops (FALSE).

The property can be both tested and set.

Example

This frame script checks the download status of a linked Flash cast member called NetFlash using the percentStreamed property. While NetFlash is downloading, the movie loops in the current frame. When NetFlash finishes downloading, the movie advances to the next frame and the loop property of the Flash movie in channel 6 is set to FALSE so that it will continue playing through to the end and then stop (imagine that this sprite has been looping while NetFlash was downloading).

on exitFrame
  if member("NetFlash").percentStreamed = 100 then
    sprite(6).loop = FALSE
    go the frame + 1
  end if
  go the frame
end
loop (Windows Media)

Usage

-- Lingo syntax
windowsMediaObjRef.loop

// JavaScript syntax
windowsMediaObjRef.loop;

Description

Windows Media property. Determines whether a movie loops (TRUE, default) or not (FALSE) after completion. Read/write.

Example

This statement specifies that the cast member Classical should loop after completion:

-- Lingo syntax
member("Classical").loop = TRUE

// JavaScript syntax
member("Classical").loop = true;

See also

Windows Media

loopBounds

Usage

-- Lingo syntax
spriteObjRef.loopBounds

// JavaScript syntax
spriteObjRef.loopBounds;

Description

QuickTime sprite property; sets the internal loop points for a QuickTime cast member or sprite. The loop points are specified as a Director list: [start\text{Time}, end\text{Time}].

The start\text{Time} and end\text{Time} parameters must meet these requirements:

• Both parameters must be integers that specify times in Director ticks.
• The values must range from 0 to the duration of the QuickTime cast member.
• The starting time must be less than the ending time.

If any of these requirements is not met, the QuickTime movie loops through its entire duration.

The loopBounds property has no effect if the movie's loop property is set to FALSE. If the loop property is set to TRUE while the movie is playing, the movie continues to play. Director uses these rules to decide how to loop the movie:

• If the ending time specified by loopBounds is reached, the movie loops back to the starting time.
• If the end of the movie is reached, the movie loops back to the start of the movie.
If the loop property is turned off while the movie is playing, the movie continues to play. Director stops when it reaches the end of the movie.

This property can be tested and set. The default setting is [0,0].

**Example**

This sprite script sets the starting and ending times for looping within a QuickTime sprite. The times are set by specifying seconds, which are then converted to ticks by multiplying by 60.

```lingo
-- Lingo syntax
on beginSprite me
sprite(me.spriteNum).loopBounds = [(16 * 60),(32 * 60)]
end

// JavaScript syntax
function beginSprite() {
  sprite(me.spriteNum).loopBounds = list((16 * 60),(32 * 60));
}
```

**loopCount**

**Usage**

```lingo
-- Lingo syntax
soundChannelObjRef.loopCount

// JavaScript syntax
soundChannelObjRef.loopCount;
```

**Description**

Sound Channel property; specifies the total number of times the current sound in a sound channel is set to loop. Read-only.

The default value of this property is 1 for sounds that are simply queued with no internal loop.

You can loop a portion of a sound by passing the parameters loopStartTime, loopEndTime, and loopCount with a queue() or setPlayList() method. These are the only methods for setting this property.

If loopCount is set to 0, the loop will repeat forever. If the sound cast member's loop property is set to TRUE, loopCount will return 0.

**Example**

This handler queues and plays two sounds in sound channel 2. The first sound, cast member introMusic, loops five times between 8 seconds and 8.9 seconds. The second sound, cast member creditsMusic, loops three times. However, no #loopStartTime and #loopEndTime are specified, so these values default to the #startTime and #endTime, respectively.

```lingo
-- Lingo syntax
on playMusic
sound(2).queue([#member:member("introMusic"), #startTime:3000, 
  #loopCount:5, #loopStartTime:8000, #loopEndTime:8900])
sound(2).queue([#member:member("creditsMusic"), #startTime:3000, 
  #endTime:3000, #loopCount:3])
sound(2).play()
end playMusic
```
// JavaScript syntax
function playMusic() {
    sound(2).queue(propList("member",member("introMusic"), "startTime",3000, "loopCount",5, "loopStartTime",8000, "loopEndTime",8900));
    sound(2).queue(propList("member",member("creditsMusic"), "startTime",3000, "endTime",3000, "loopCount",3));
    sound(2).play();
}

See also
loopEndTime, loopStartTine, queue(), setPlayList(), Sound Channel

loopEndTime

Usage
-- Lingo syntax
soundChannelObjRef.loopEndTime

// JavaScript syntax
soundChannelObjRef.loopEndTime;

Description
Sound Channel property; specifies the end time, in milliseconds, of the loop set in the current sound playing in a sound channel. Read-only.

The value of this property is a floating-point number, allowing you to measure and control sound playback to fractions of a millisecond.

This property can only be set when passed as a property in a queue() or setPlaylist() command.

Example
This handler plays sound cast member introMusic in sound channel 2. Playback loops five times between the 8 seconds point and the 8.9 second point in the sound.

-- Lingo syntax
on playMusic
    sound(2).play([#member:member("introMusic"), #startTime:3000, #loopCount:5 \ #loopStartTime:8000, #loopEndTime:8900])
end playMusic

// JavaScript syntax
function playMusic() {
    sound(2).play(propList("member",member("introMusic"), "startTime",3000, "loopCount",5, "loopStartTime",8000, "loopEndTime",8900));
}

See also
queue(), setPlayList(), Sound Channel
loopsRemaining

Usage
   -- Lingo syntax
   soundChannelObjRef.loopsRemaining

   // JavaScript syntax
   soundChannelObjRef.loopsRemaining;

Description
Sound Channel property; specifies the number of times left to play a loop in the current sound playing in a sound channel. Read-only.

If the sound had no loop specified when it was queued, this property is 0. If this property is tested immediately after a sound starts playing, it returns one less than the number of loops defined with the #loopCount property in the queue() or setPlayList() methods.

See also
   loopCount, queue(), setPlayList(), Sound Channel

loopStartTime

Usage
   -- Lingo syntax
   soundChannelObjRef.loopStartTime

   // JavaScript syntax
   soundChannelObjRef.loopStartTime;

Description
Sound Channel property; specifies the start time, in milliseconds, of the loop for the current sound being played by a sound channel. Read-only.

Its value is a floating-point number, allowing you to measure and control sound playback to fractions of a millisecond. The default is the startTime of the sound if no loop has been defined.

This property can only be set when passed as a property in a queue() or setPlaylist() methods.

Example
This handler plays sound cast member introMusic in sound channel 2. Playback loops five times between two points 8 seconds and 8.9 seconds into the sound.

   -- Lingo syntax
   on playMusic
      sound(2).play([#member:member("introMusic"), #startTime:3000, #loopCount:5 \ #loopStartTime:8000, #loopEndTime:8900])
   end playMusic

   // JavaScript syntax
   function playMusic() {
      sound(2).play(propList("member",member("introMusic"), "startTime",3000, "loopCount",5, "loopStartTime",8000, "loopEndTime",8900));
   }

   See also
   queue(), setPlayList(), Sound Channel, startTime
**magnitude**

**Usage**

\[ \text{whichVector.magnitude} \]

**Description**

3D property; returns the magnitude of a vector. The value is a floating-point number. The magnitude is the length of a vector and is always greater than or equal to 0.0. \((\text{vector}(0, 0, 0) \text{ equals } 0.)\)

**Example**

This statement shows that the magnitude of MyVec1 is 100.0000 and the magnitude of MyVec2 is 141.4214.

\[
\begin{align*}
\text{MyVec1} &= \text{vector}(100, 0, 0) \\
\text{put MyVec1.magnitude} \\
&\quad -- 100.0000 \\
\text{MyVec2} &= \text{vector}(100, 100, 0) \\
\text{put MyVec2.magnitude} \\
&\quad -- 141.4214
\end{align*}
\]

**See also**

`length (3D), identity()`

**margin**

**Usage**

\[
\begin{align*}
&\quad -- \text{Lingo syntax} \\
&\quad \text{memberObjRef.margin} \\
// \text{JavaScript syntax} \\
&\quad \text{memberObjRef.margin;}
\end{align*}
\]

**Description**

Field cast member property; determines the size, in pixels, of the margin inside the field box.

**Example**

The following statement sets the margin inside the box for the field cast member Today's News to 15 pixels:

\[
\begin{align*}
&\quad -- \text{Lingo syntax} \\
&\quad \text{member("Today's News").margin = 15} \\
// \text{JavaScript syntax} \\
&\quad \text{member("Today's News").margin = 15;}
\end{align*}
\]
markerList

Usage

-- Lingo syntax
_movie.markerList

// JavaScript syntax
_movie.markerList;

Description

Movie property; contains a script property list of the markers in the Score. Read-only.

The list is of the format:

frameNumber: "markerName"

Example

This statement displays the list of markers in the Message window:

-- Lingo syntax
put(_movie.markerList)

// JavaScript syntax
put(_movie.markerList);

See also

Movie

mask

Usage

-- Lingo syntax
memberObjRef.mask

// JavaScript syntax
memberObjRef.mask;

Description

Cast member property; specifies a black-and-white (1-bit) cast member to be used as a mask for media rendered direct to Stage with media appearing in the areas where the mask's pixels are black. The mask property lets you benefit from the performance advantages of a direct-to-Stage digital video while playing a QuickTime movie in a nonrectangular area. The mask property has no effect on non–direct-to-Stage cast members.

Director always aligns the registration point of the mask cast member with the upper left of the QuickTime movie sprite. Be sure to reset the registration point of a bitmap to the upper left corner, as it defaults to the center. The registration point of the QuickTime member cannot be reset from the upper left corner. The mask cast member can't be moved and is not affected by the center and crop properties of its associated cast member.

For best results, set a QuickTime cast member's mask property before any of its sprites appear on the Stage in the on beginSprite event handler. Setting or changing the mask property while the cast member is on the Stage can have unpredictable results (for example, the mask may appear as a freeze frame of the digital video at the moment the mask property took effect).
Masking is an advanced feature; you may need to experiment to achieve your goal. This property can be tested and set. To remove a mask, set the `mask` property to 0.

**Example**

This frame script sets a mask for a QuickTime sprite before Director begins to draw the frame:

```lingo
-- Lingo syntax
on prepareFrame
    member("Peeping Tom").mask = member("Keyhole")
end

// JavaScript syntax
function prepareFrame() {
    member("Peeping Tom").mask = member("Keyhole");
}

See also
invertMask```

**maxInteger**

**Usage**

```
the maxInteger
```

**Description**

System property; returns the largest whole number that is supported by the system. On most personal computers, this is 2,147,483,647 (2 to the thirty-first power, minus 1).

This property can be useful for initializing boundary variables before a loop or for limit testing.

To use numbers larger than the range of addressable integers, use floating-point numbers instead. They aren’t processed as quickly as integers, but they support a greater range of values.

**Example**

This statement generates a table, in the Message window, of the maximum decimal value that can be represented by a certain number of binary digits:

```lingo
on showMaxValues
    b = 31
    v = the maxInteger
    repeat while v > 0
        put b && "-" && v
        b = b-1
        v = v/2
    end repeat
end```
**maxSpeed**

**Usage**

```plaintext
member(whichCastmember).modelResource(whichModelResource).\emitter.maxSpeed
```

**Description**

3D property; when used with a model resource whose type is `#particle`, allows you to get and set the maximum speed at which particles are emitted. Each particle's initial velocity is randomly selected between the emitter's `minSpeed` and `maxSpeed` properties.

The value is a floating-point number and must be greater than 0.0.

**Example**

In this example, ThermoSystem is a model resource of the type `#particle`. This statement sets the `maxSpeed` property of ThermoSystem to 15, which causes the fastest particles of ThermoSystem to move fairly quickly. Within a given particle system, the faster a particle moves, the farther it will travel.

```plaintext
member("Fires").modelResource("ThermoSystem").emitter.maxSpeed=15
```

**See also**

`minSpeed`, `emitter`

**media**

**Usage**

--- Lingo syntax

```plaintext
memberObjRef.media
```

--- JavaScript syntax

```plaintext
memberObjRef.media;
```

**Description**

Member property; identifies the specified cast member as a set of numbers. Read/write.

Because setting this property can use large amounts of memory, it is best used during authoring only.

You can use the `media` property to copy the content of one cast member into another cast member by setting the second member's `media` value to the `media` value for the first member.

For a film loop cast member, the `media` property specifies a selection of frames and channels in the Score.

To swap media in a projector, it is more efficient to set the `member` sprite property.
Example
This statement copies the content of the cast member Sunrise into the cast member Dawn by setting the `media` member property value for Dawn to the `media` member property value for Sunrise:

-- Lingo syntax
member("Dawn").media = member("Sunrise").media

// JavaScript syntax
member("Dawn").media = member("Sunrise").media;

See also
Member

mediaReady

Usage
-- Lingo syntax
memberObjRef.mediaReady

// JavaScript syntax
memberObjRef.mediaReady;

Description
Member property; determines whether the contents of a cast member, a movie or cast library file, or a linked cast member is downloaded from the Internet and is available on the local disk (true) or not (false). Read-only.

This property is useful only when streaming a movie or cast library file. Movie streaming is activated by setting the Movie:Playback properties in the Modify menu to Play While Downloading Movie (default setting).

For a demonstration of the `mediaReady` property, see the sample movie Streaming Shockwave in Director Help.

Example
This statement changes cast members when the desired cast member is downloaded and available locally:

-- Lingo syntax
if member("background").mediaReady = true then
    sprite(2).member = member("background").number
end if

// JavaScript syntax
if (member("background").mediaReady == true) {
    sprite(2).member = member("background").number;
}

See also
Member
mediaStatus (DVD)

Usage

-- Lingo syntax
dvdObjRef.mediaStatus

// JavaScript syntax
dvdObjRef.mediaStatus;

Description

DVD property; returns a symbol that indicates the current state of the DVD player. Read-only. Possible symbols include the following:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#stopped</td>
<td>The DVD is stopped.</td>
</tr>
<tr>
<td>#playing</td>
<td>The DVD is playing.</td>
</tr>
<tr>
<td>#paused</td>
<td>The DVD is paused.</td>
</tr>
<tr>
<td>#scanning</td>
<td>The DVD is scanning.</td>
</tr>
<tr>
<td>#uninitialized</td>
<td>The DVD is not initialized.</td>
</tr>
<tr>
<td>#volumeInvalid</td>
<td>The DVD specified is not valid.</td>
</tr>
<tr>
<td>#volumeUnknown</td>
<td>The DVD does not exist or there is no disc in the drive.</td>
</tr>
<tr>
<td>#systemSoftwareMissing</td>
<td>The DVD decoders are not installed.</td>
</tr>
<tr>
<td>#systemSoftwareError</td>
<td>The system software required to play the DVD reported an error.</td>
</tr>
</tbody>
</table>

See also

DVD

mediaStatus (RealMedia, Windows Media)

Usage

-- Lingo syntax
memberOrSpriteObjRef.mediaStatus

// JavaScript syntax
memberOrSpriteObjRef.mediaStatus;

Description

RealMedia and Windows Media cast member and sprite property; allows you to get a symbol representing the state of the RealMedia or Windows Media stream. Read-only.

The value of this property can change during playback.

Valid values for this property are as follows:

- #closed indicates that the RealMedia or Windows Media cast member is not active. The mediaStatus value remains #closed until playback is initiated.
- #connecting indicates that a connection to the RealMedia or Windows Media stream is being established.
• #opened indicates that a connection to the RealMedia or Windows Media stream has been established and is open. This is a transitory state that is very quickly followed by #buffering.
• #buffering indicates that the RealMedia or Windows Media stream is being downloaded into the playback buffer. When buffering is complete (percentBuffered equals 100), the stream begins to play if the pausedAtStart property is FALSE. For more information, see percentBuffered.
• #playing indicates that the RealMedia or Windows Media stream is currently playing.
• #seeking indicates that play was interrupted by the seek command.
• #paused indicates that play has been interrupted, possibly by the user clicking the Stop button in the RealMedia or Windows Media viewer, or by a script invoking the pause() method.
• #error indicates that the stream could not be connected, buffered, or played for some reason. The lastError property reports the actual error.

Depending on the cast member's state (RealMedia) value, a different mediaStatus property value is returned. Each mediaStatus value corresponds to only one state value.

Example

The following examples show that the RealMedia element in sprite 2 and the cast member Real is playing.

-- Lingo syntax
put(sprite(2).mediaStatus) -- #playing
put(member("Real").mediaStatus) -- #playing

// JavaScript syntax
put(sprite(2).mediaStatus); // #playing
put(member("Real").mediaStatus); // #playing

See also
state (RealMedia), percentBuffered, lastError

mediaXtraList

Usage

-- Lingo syntax
_player.mediaXtraList

// JavaScript syntax
_player.mediaXtraList;

Description

Player property; returns a linear list of all media Xtra extensions available to the Director player. Read-only.

Example

This statement displays in the Message window all media Xtra extensions that are available to the Director Player.

-- Lingo syntax
put(_player.mediaXtraList)

// JavaScript syntax
put(_player.mediaXtraList);
See also
Media Types, Player, scriptingXtraList, toolXtraList, transitionXtraList, xtraList (Player)

**member**

**Usage**

member(whichCastmember).texture(whichTexture).member
member(whichCastmember).model(whichModel).shader.texture.member
member(whichCastmember).model(whichModel).shaderList[shaderListIndex].textureList[textureListIndex].member

**Description**

3D texture property; if the texture's type is #fromCastMember, this property indicates the cast member that is used as the source for a texture.

This property can be tested and set.

If the texture's type is #importedFromFile, this property value is void and cannot be set. If the texture's type is #fromImageObject, this property value is void, but it can be set.

**Example**

This Lingo adds a new texture. The second statement shows that the cast member used to create the texture named gbTexture was member 16 of cast 1.

```lingo
member("scene").newTexture("gbTexture", #fromCastmember, 
    member(16, 1))
put member("scene").texture("gbTexture").member
-- (member 16 of castLib 1)
```

**member (Cast)**

**Usage**

-- Lingo syntax
castObjRef.member[memberNameOrNum]

// JavaScript syntax
castObjRef.member[memberNameOrNum]

**Description**

Cast library property; provides indexed or named access to the members of a cast library.

Read-only.

The `memberNameOrNum` argument can be a string that specifies the cast member by name or an integer that specifies the cast member by number.

**Example**

The following example provides access to the second cast member in the cast library named Internal.

-- Lingo syntax
myMember = castLib("Internal").member[2]

// JavaScript syntax
var myMember = castLib("Internal").member[2];
member (Movie)

Usage
-- Lingo syntax
_movie.member[memberNameOrNum]

// JavaScript syntax
_movie.member[memberNameOrNum];

Description
Movie property; provides indexed or named access to the members of a movie's cast library.
Read-only.

The memberNameOrNum argument can be a string that specifies the cast member by name or an
integer that specifies the cast member by number.

Example
The following statement accesses a cast member using both named and numbered access, and sets
the result to the variable myMember.
-- Lingo syntax
myMember = _movie.member[2] -- using numbered access
myMember = _movie.member["Athlete"] -- using named access

// JavaScript syntax
var myMember = _movie.member[2]; // using numbered access;
var myMember = _movie.member["Athlete"]; // using named access;

See also
Cast Library, Movie

member (Sound Channel)

Usage
-- Lingo syntax
soundChannelObjRef.member

// JavaScript syntax
soundChannelObjRef.member;

Description
Sound Channel property; specifies the sound cast member currently playing in a sound channel.
Read-only.

This property returns VOID (Lingo) or null (JavaScript syntax) if no sound is being played.

Example
This statement displays the name of the member of the sound playing in sound channel 2 in the
Message window:
-- Lingo syntax
put(sound(2).member)

// JavaScript syntax
put(sound(2).member);
member (Sprite)

Usage

-- Lingo syntax
spriteObjRef.member

// JavaScript syntax
spriteObjRef.member;

Description

Sprite property; specifies a sprite's cast member and cast library. Read/write.

The member Sprite property differs from the spriteNum Sprite property, which specifies only the
sprite's number to identify its location in the cast library but doesn't specify the cast library itself.

The member property also differs from the Mouse object's mouseMember property, which does not
specify a sprite's cast library.

When assigning a sprite's member property, use one of the following formats:

• Specify the full cast member and cast library description (spriteObjRef.member =
  member(intMemberNum \{, castLibraryNameOrNum\})).
• Specify the cast member name (spriteObjRef.member = member("stringMemberName")).
• Specify the unique integer that includes all cast libraries and corresponds to the mouseMember
  property (spriteObjRef.member = 132).

If you use only the cast member name, Director finds the first cast member that has that name in
all current cast libraries. If the name is duplicated in two cast libraries, only the first name is used.

To specify a cast member by number when there are multiple casts, use the memberNum Sprite
property, which changes the member's position in its cast library without affecting the sprite's cast
library (spriteObjRef.memberNum = 10).

The cast member assigned to a sprite channel is only one of that sprite's properties; other
properties vary by the type of media element in that channel in the Score. For example, if you
replace a bitmap with an unfilled shape by setting the member Sprite property, the shape sprite's
lineSize property doesn't automatically change, and you probably won't see the shape.

Similar sprite property mismatches can occur if you change the member of a field sprite to a
video. It's generally more useful and predictable to replace cast members with similar cast
members. For example, replace bitmap sprites with bitmap cast members.

Example

This statement assigns cast member 3 of cast number 4 to sprite 15:

-- Lingo syntax
sprite(15).member = member(3, 4)

// JavaScript syntax
sprite(15).member = member(3, 4);
The following handler uses the `mouseMember` function with the `sprite.member` property to find if the mouse is over a particular sprite:

---

**Lingo syntax**

```lingo
on exitFrame
    mm = _mouse.mouseMember
    target = sprite(1).member
    if (target = mm) then
        put("Above the hotspot.")
        _movie.go(_movie.frame)
    end if
end
```

// JavaScript syntax

```javascript
function exitFrame()
{
    var mm = _mouse.mouseMember;
    var target = sprite(1).member;
    if (target == mm) {
        put("Above the hotspot.");
        _movie.go(_movie.frame);
    }
}
```

---

**See also**

`lineSize`, `mouseMember`, `Sprite`, `spriteNum`

**memorySize**

**Usage**

the `memorySize`

**Description**

System property; returns the total amount of memory allocated to the program, whether in use or free memory. This property is useful for checking minimum memory requirements. The value is given in bytes.

- In Windows, the value is the total physical memory available; on the Macintosh, the value is the entire partition assigned to the application.

**Example**

This statement checks whether the computer allocates less than 500K of memory and, if it does, displays an alert:

```lingo
if the memorySize < 500 * 1024 then alert "There is not enough memory to run this movie."
```

**See also**

`freeBlock()`, `freeBytes()`, `ramNeeded()`, `size`
meshDeform (modifier)

Usage
member(whichCastmember).model(whichModel).meshDeform.propertyName

Description
3D modifier; allows control over the various aspects of the referenced model's mesh structure.
Once you have added the #meshDeform modifier (using the addModifier command) to a model
you have access to the following properties of the #meshDeform modifier:

Note: For more detailed information about the following properties see the individual property entries
referenced in the see also section of this entry.

- `face.count` returns the total number of faces in the referenced model.
- `mesh.count` returns the number of meshes in the referenced model.
- `mesh[index]` allows access to the properties of the specified mesh.

Example
The following statement displays the number of faces in the model named gbFace:
```
put member(“3D World”).model(“gbFace”).meshDeform.face.count
-- 432
```
The following statement displays the number of meshes in the model named gbFace:
```
put member(“3D World”).model(“gbFace”).meshDeform.mesh.count
-- 2
```
The following statement displays the number of faces in the second mesh of the model
named gbFace:
```
put member(“3D World”).model(“gbFace”).meshDeform.mesh[2].face.count
-- 204
```

See also
mesh (property), addModifier

milliseconds

Usage

-- Lingo syntax
_system.milliseconds

// JavaScript syntax
_system.milliseconds;

Description
System property; returns the current time in milliseconds (1/1000 of a second). Read-only.
Counting begins from the time the computer is started.
Example

This statement converts milliseconds to seconds and minutes by dividing the number of milliseconds by 1000 and dividing that result by 60, and then sets the variable `currentMinutes` to the result:

-- Lingo syntax
```
currentSeconds = _system.milliseconds/1000
currentMinutes = currentSeconds/60
```
// JavaScript syntax
```
var currentSeconds = _system.milliseconds/1000;
var currentMinutes = currentSeconds/60;
```

The resolution accuracy of the count is machine and operating system dependent.

This handler counts the milliseconds and posts an alert if you've been working too long:

-- Lingo syntax
```
on idle
  if (_system.milliseconds > (1000 * 60 * 60 * 4)) then
    _player.alert("Take a break")
  end if
end
```
// JavaScript syntax
```
function idle() {
  if (_system.milliseconds > (1000 * 60 * 60 * 4)) {
    _player.alert("Take a break");
  }
}
```

See also

System

minSpeed

Usage

```
member(whichCastmember).modelResource(whichModelResource).
  emitter.minSpeed
```

Description

3D property; when used with a model resource whose type is `@particle`, allows you to get and set the minimum speed at which particles are emitted. Each particle's initial velocity is randomly selected between the emitter's `minSpeed` and `maxSpeed` properties.

The value is a floating-point number and must be greater than 0.0.

Example

In this example, ThermoSystem is a model resource of the type `@particle`. This statement sets the `minSpeed` property of ThermoSystem to 5, which causes the slowest particles of ThermoSystem to move somewhat slowly. Within a given particle system, the slower a particle moves, the shorter the distance it will travel.

```
member("Fires").modelResource("ThermoSystem").emitter.
  minSpeed = 5
```

See also

`maxSpeed`, `emitter`
missingFonts

Usage
member(textCastMember).missingFonts

Description
Text cast member property; this property contains a list of the names of the fonts that are referenced in the text, but not currently available on the system.

This allows the developer to determine during run time if a particular font is available or not.

This property can be tested but not set.

See also
substituteFont

mode (emitter)

Usage
member(whichCastmember).modelResource(whichModelResource).\emitter.mode

Description
3D property; when used with a model resource whose type is #particle, allows you to both get and set the mode property of the resource's particle emitter.

This property can have the value #burst or #stream (default). A mode value of #burst causes all particles to be emitted at the same time, while a value of #stream causes a group of particles to be emitted at each frame. The number of particles emitted in each frame is determined using the following equation:

\[
particlesPerFrame = \text{resourceObject.emitter.numParticles} \times \left(\frac{\text{resourceObject.lifetime}}{\text{millisecondsPerRenderedFrame}}\right)
\]

Example
In this example, ThermoSystem is a model resource of the type #particle. This statement sets the emitter.mode property of ThermoSystem to #burst, which causes the particles of ThermoSystem to appear in bursts. To create a single burst of particles, set emitter.mode = #burst and emitter.loop = 0.

member("Fires").modelResource("ThermoSystem").emitter.mode = #burst

See also
dispenser
**mode (collision)**

**Usage**
member(whichCastmember).model(whichModel).collision.mode

**Description**
3D collision modifier property; indicates the geometry to be used in the collision detection algorithm. Using simpler geometry such as the bounding sphere leads to better performance. The possible values for this property are:

- `#mesh` uses the actual mesh geometry of the model's resource. This gives one-triangle precision and is usually slower than `#box` or `#sphere`.
- `#box` uses the bounding box of the model. This is useful for objects that can fit more tightly in a box than in a sphere, such as a wall.
- `#sphere` is the fastest mode, because it uses the bounding sphere of the model. This is the default value for this property.

**Example**
These statements add the collision modifier to the model named `your Model` and set the mode property to `#mesh`:

```javascript
member("3d").model("yourModel").addModifier(#collision)
member("3d").model("yourModel").collision.mode = #mesh
```

**model**

**Usage**
member(whichCastmember).model(whichModel)
member(whichCastmember).model[index]
member(whichCastmember).model.count
member(whichCastmember).model(whichModel).propertyName
member(whichCastmember).model[index].propertyName

**Description**
3D command; returns the model found within the referenced cast member that has the name specified by `whichModel`, or is found at the index position specified by `index`. If no model exists for the specified parameter, the command returns `void`. As `model.count`, the command returns the number of models found within the referenced cast member. This command also allows access to the specified model's properties.

Model name comparisons are not case-sensitive. The index position of a particular model may change when objects at lower index positions are deleted.

If no model is found that uses the specified name or no model is found at the specified index position then this command returns `void`.

**Example**
This statement stores a reference to the model named Player Avatar in the variable `thismodel`:

```javascript
thismodel = member("3DWorld").model("Player Avatar")
```
This statement stores a reference to the eighth model of the cast member named 3DWorld in the variable thismodel.

```
thismodel = member("3DWorld").model[8]
```

This statement shows that there are four models in the member of sprite 1.

```
put sprite(1).member.model.count
-- 4
```

### modelA

**Usage**

```
collisionData.modelA
```

**Description**

3D `collisionData` property; indicates one of the models involved in a collision, the other model being `modelB`.

The `collisionData` object is sent as an argument with the `#collideWith` and `#collideAny` events to the handler specified in the `registerForEvent`, `registerScript`, and `setCollisionCallback` commands.

The `#collideWith` and `#collideAny` events are sent when a collision occurs between models to which collision modifiers have been added. The `resolve` property of the models’ modifiers must be set to `TRUE`.

This property can be tested but not set.

**Example**

This example has three parts. The first part is the first line of code, which registers the `#putDetails` handler for the `#collideAny` event. The second part is the `#putDetails` handler. When two models in the cast member named MyScene collide, the `#putDetails` handler is called and the `collisionData` argument is sent to it. This handler displays the `modelA` and `modelB` properties of the `collisionData` object in the message window. The third part of the example shows the results from the message window. These show that the model named GreenBall was `modelA` and the model named YellowBall was `modelB` in the collision.

```
member("MyScene").registerForEvent(#collideAny, #putDetails, 0)
on putDetails me, collisionData
    put collisionData.modelA
    put collisionData.modelB
end
-- model("GreenBall")
-- model("YellowBall")
```

**See also**

`registerScript()`, `registerForEvent()`, `sendEvent`, `modelB`, `setCollisionCallback()`
modelB

Usage
    collisionData.modelB

Description
3D collisionData property; indicates one of the models involved in a collision, the other model being modelA.

The collisionData object is sent as an argument with the #collideWith and #collideAny events to the handler specified in the registerForEvent, registerScript, and setCollisionCallback commands.

The #collideWith and #collideAny events are sent when a collision occurs between models to which collision modifiers have been added. The resolve property of the models' modifiers must be set to TRUE.

This property can be tested but not set.

Example
This example has three parts. The first part is the first line of code, which registers the #putDetails handler for the #collideAny event. The second part is the #putDetails handler. When two models in the cast member named MyScene collide, the #putDetails handler is called and the collisionData argument is sent to it. This handler displays the modelA and modelB properties of the collisionData object in the message window. The third part of the example shows the results from the message window. These show that the model named GreenBall was modelA and the model named YellowBall was modelB in the collision.

    member("MyScene").registerForEvent(#collideAny, #putDetails, 0)
    on putDetails me, collisionData
        put collisionData.modelA
        put collisionData.modelB
    end
    -- model("GreenBall")
    -- model("YellowBall")

See also
    registerScript(), registerForEvent(), sendEvent, modelA, collisionNormal, setCollisionCallback()
modelResource

Usage
member(whichCastmember).modelResource(whichModelResource)
member(whichCastmember).modelResource[index]
member(whichCastmember).modelResource.count
member(whichCastmember).modelResource(whichModelResource).\prop
member(whichCastmember).modelResource[index].prop

Description
3D command; returns the model resource found within the referenced cast member that has the
name specified by whichModelResource, or is found at the index position specified by the
index parameter. If no model resource exists for the specified parameter, the command returns void. As modelResource.count, the command returns the number of model resources found
within the referenced cast member. This command also allows access to the specified
model resource's properties.

Model resource name string comparisons are not case-sensitive. The index position of a particular
model resource may change when objects at lower index positions are deleted.

Example
This statement stores a reference to the model resource named HouseA in the variable
thismodelResource.
thismodelResource = member("3DWorld").modelResource("HouseA")

This statement stores a reference to the fourteenth model resource of the cast member named
3DWorld in the variable thismodelResource.
thismodelResource = member("3DWorld").modelResource[14]

This statement shows that there are ten model resources in the member of sprite 1.
put sprite(1).member.modelResource.count
-10

modified

Usage
-- Lingo syntax
memberObjRef.modified

// JavaScript syntax
memberObjRef.modified;

Description
Member property; indicates whether a cast member has been modified since it was read from a
movie file. Read-only.
• When the modified property is TRUE (1), the cast member has been modified since it was read
from the movie file.
• When the modified property is FALSE (0), the cast member has not been modified since it was
read from the movie file.
Example

This statement tests whether the cast member Introduction has been modified since it was read from the movie file:

-- Lingo syntax
if (member("Introduction").modified) then
    _player.alert("Introduction has been modified")
else
    _player.alert("Introduction has not been modified")
end if

// JavaScript syntax
if (member("Introduction").modified) {
    _player.alert("Introduction has been modified");
} else {
    _player.alert("Introduction has not been modified");
}

See also

Member

modifiedBy

Usage

-- Lingo syntax
memberObjRef.modifiedBy

// JavaScript syntax
memberObjRef.modifiedBy;

Description

Member property; records the name of the user who last edited the cast member. Read-only.

The name is taken from the user name information provided during Director installation. You can change this information in the Director General Preferences dialog box.

This property is useful for tracking and coordinating Director projects with more than one author, and may also be viewed in the Property inspector's Member tab.

Example

This statement displays the name of the person who last modified cast member 1:

-- Lingo syntax
put(member(1).modifiedBy)

// JavaScript syntax
put(member(1).modifiedBy);

See also

Member
modifiedDate

Usage

-- Lingo syntax
memberObjRef.modifiedDate

// JavaScript syntax
memberObjRef.modifiedDate;

Description

Member property; indicates the date and time that the cast member was last changed, using the system time on the authoring computer. Read-only.

This property is useful for tracking and coordinating Director projects. It can also be viewed in the Property inspector’s Member tab and the Cast window list view.

Example

This statement displays the date of the last change to cast member 1:

-- Lingo syntax
put(member(1).modifiedDate)

// JavaScript syntax
put(member(1).modifiedDate);

See also

Member

modifier

Usage

member(whichCastmember).model(whichModel).modifier
member(whichCastmember).model(whichModel).modifier.count

Description

3D model property; returns a list of modifiers that are attached to the specified model. As modifier.count, the command returns the number of modifiers attached to the model.

If both the toon and inker modifiers are applied to a model, only the first one that was added to the model is returned.

This property can be tested but not set. Use the addModifier and removeModifier commands to add and remove modifiers from models.

Example

This statement shows which modifiers are attached to the model named Juggler:

put member("ParkScene").model("Juggler").modifier
-- @[bonesPlayer, #lod]

See also

modifier[], modifiers, addModifier, removeModifier
modifier[]

Usage
member(whichCastmember).model(whichModel).modifier[index]

Description
3D model property; returns the type of the modifier found at the position specified by index within the model's attached modifier list. The value returned is a symbol.
If no modifier is found at the specified position then this property's value is void.
To obtain information about a model's attached modifier list use the modifier property.
Direct access into an attached modifier's properties is not supported through the use of this command.

Example
put member("3d world").model("box").modifier[1]
-- #lod

See also
modifier, modifiers, addModifier, removeModifier

modifiers

Usage
getRendererServices().modifiers

Description
Global 3D property; returns a list of modifiers available to models within 3D cast members.

Example
This statement returns the list of all currently available modifiers:
put getRendererServices().modifiers
-- [#collision, #bonesPlayer, #keyFramePlayer, #toon, #lod, #meshDeform, #sds, #inker]

See also
getRendererServices(). addModifier

mostRecentCuePoint

Usage
-- Lingo syntax
spriteObjRef.mostRecentCuePoint

// JavaScript syntax
spriteObjRef.mostRecentCuePoint;

-- Lingo syntax
spriteObjRef.mostRecentCuePoint

// JavaScript syntax
spriteObjRef.mostRecentCuePoint;
Description

Sound channel and sprite property; for sound sprites, QuickTime digital video, and Xtra extensions that support cue points, indicates the number that identifies the most recent cue point passed in the sprite or sound. The value is the cue point’s ordinal number. If no cue points have been passed, the value is 0.

Shockwave Audio (SWA) sounds can appear as sprites in sprite channels, but they play sound in a sound channel. It is recommended that you refer to SWA sound sprites by their sprite channel number rather than their sound channel number.

Example

This statement tells the Message window to display the number for the most recent cue point passed in the sprite in sprite channel 1:

-- Lingo syntax
put sprite(1).mostRecentCuePoint

// JavaScript syntax
put(sprite(1).mostRecentCuePoint);

This statement returns the ordinal number of the most recently passed cue point in the currently playing sound in sound channel 2:

-- Lingo syntax
put sound(2).mostRecentCuePoint

// JavaScript syntax
put(sound(2).mostRecentCuePoint);

See also
cuePointNames, isPastCuePoint(), cuePointTimes, on cuePassed

motion

Usage

member(whichCastmember).motion(whichMotion)
member(whichCastmember).motion[index]
member(whichCastmember).motion.count

Description

3D command; returns the motion found within the referenced cast member that has the name specified by whichMotion, or is found at the index position specified by the index. As motion.count, this property returns the total number of motions found within the cast member.

Object name string comparisons are not case-sensitive. The index position of a particular motion may change when objects at lower index positions are deleted.

If no motion is found that uses the specified name or no motion is found at the specified index position then this command returns void.

Example

thisMotion = member("3D World").motion("Wing Flap")
thisMotion = member("3D World").motion[7]
put member("scene").motion.count
-- 2

See also
duration (3D), map (3D)
**motionQuality**

**Usage**

-- Lingo syntax
spriteObjRef.motionQuality

// JavaScript syntax
spriteObjRef.motionQuality;

**Description**

QuickTime VR sprite property; the codec quality used when the user clicks and drags the QuickTime VR sprite. The property's value can be #minQuality, #maxQuality, or #normalQuality.

This property can be tested and set.

**Example**

This statement sets the motionQuality of sprite 1 to #minQuality.

-- Lingo syntax
sprite(1).motionQuality = #minQuality

// JavaScript syntax
sprite(1).motionQuality = symbol("minQuality");

**mouseChar**

**Usage**

-- Lingo syntax
_mouse.mouseChar

// JavaScript syntax
_mouse.mouseChar;

**Description**

Mouse property; for field sprites, contains the number of the character that is under the pointer when the property is called. Read-only.

The count is from the beginning of the field. If the mouse pointer is not over a field or is in the gutter of a field, the result is -1.

The value of mouseChar can change in a handler or loop. If a handler or loop uses this property multiple times, it's usually a good idea to call the property once and assign its value to a local variable.
Example

This statement determines whether the pointer is over a field sprite and changes the content of the field cast member Instructions to “Please point to a character.” when it is not:

-- Lingo syntax
if (_mouse.mouseChar = -1) then
    member("Instructions").text = "Please point to a character."
end if

// JavaScript syntax
if (_mouse.mouseChar == -1) {
    member("Instructions").text = "Please point to a character."
}

This statement assigns the character under the pointer in the specified field to the variable currentChar:

-- Lingo syntax
currentChar = member(_mouse.mouseMember).char[_mouse.mouseChar]

// JavaScript syntax
var currentChar = member(_mouse.mouseMember).getProp("char", _mouse.mouseChar);

See also
Mouse, mouseItem, mouseLine

mouseDown

Usage

-- Lingo syntax
_mouse.mouseDown

// JavaScript syntax
_mouse.mouseDown;

Description

Mouse property; indicates whether the mouse button is currently being pressed (TRUE) or not (FALSE). Read-only.

Example

The following mouseEnter handler that is attached to a sprite calls one handler if the mouse is not down when the mouse enters the sprite, and calls a different handler if the mouse is not down when the mouse enters the sprite.

-- Lingo syntax
on mouseEnter
    if (_mouse.mouseDown) then
        runMouseDownScript
    else
        runMouseUpScript
    end if
end

// JavaScript syntax
function mouseEnter() {
    if (_mouse.mouseDown) {
        runMouseDownScript();
    }
    else {
        runMouseUpScript();
    }
}

See also
Mouse, on mouseDown (event handler), mouseH, mouseUp, on mouseUp (event handler), mouseV

mouseDownScript

Usage
the mouseDownScript

Description
System property; specifies the Lingo that is executed when the mouse button is pressed. The Lingo is written as a string, surrounded by quotation marks and can be a simple statement or a calling script for a handler. The default value is EMPTY, which means that the mouseDownScript property has no Lingo assigned to it.

When the mouse button is pressed and the mouseDownScript property is defined, Lingo executes the instructions specified for the mouseDownScript property first. No other on mouseDown handlers are executed, unless the instructions include the pass command so that the mouseDown message can be passed to other objects in the movie.

Setting the mouseDownScript property performs the same function as the when keyDown then command in earlier versions of Director.

To turn off the instructions you've specified for the mouseDownScript property, use the statement set the mouseDownScript to empty.

This property can be tested and set.

Example
In this statement, when the user clicks the mouse button, the playhead always branches to the next marker in the movie:
the mouseDownScript = "go next"

In this statement, when the user clicks anywhere on the Stage, the computer beeps:
the mouseDownScript = "if the clickOn = 0 then beep"

The following statement sets mouseDownScript to the custom handler myCustomHandler. A Lingo custom handler must be enclosed in quotation marks when used with the mouseDownScript property.
the mouseDownScript = "myCustomHandler"

See also
stopEvent(), mouseUpScript, on mouseDown (event handler), on mouseUp (event handler)
**mouseH**

**Usage**

-- Lingo syntax

_`_mouse.mouseH

// JavaScript syntax

_`_mouse.mouseH;

**Description**

Mouse property; indicates the horizontal position of the mouse pointer. Read-only.

The value of `mouseH` is the number of pixels the cursor is positioned from the left edge of the Stage.

The `mouseH` property is useful for moving sprites to the horizontal position of the mouse pointer and checking whether the pointer is within a region of the Stage. Using the `mouseH` and `mouseV` properties together, you can determine the cursor's exact location.

**Example**

This handler moves sprite 10 to the mouse pointer location and updates the Stage when the user clicks the mouse button:

-- Lingo syntax

on mouseDown
    sprite(10).locH = _mouse.mouseH
    sprite(10).locV = _mouse.mouseV
end

// JavaScript syntax

function mouseDown() {
    sprite(10).locH = _mouse.mouseH;
    sprite(10).locV = _mouse.mouseV;
}

This statement tests whether the pointer is more than 10 pixels to the right or left of a starting point and, if it is, sets the variable `Far` to TRUE:

-- Lingo syntax

startH = 7

if (abs(_mouse.mouseH - startH) > 10) then
    Far = TRUE
end if

// JavaScript syntax

var startH = 7;

if (Math.abs(_mouse.mouseH - startH) > 10) {
    var Far = true;
}

**See also**

`locH`, `locV`, `Mouse`, `mouseLoc`, `mouseV`
mouselItem

Usage

-- Lingo syntax
.mouse.mouselItem

// JavaScript syntax
.mouse.mouselItem;

Description

Mouse property; contains the number of the item under the pointer when the property is called
and the pointer is over a field sprite. Read-only.

An item is any sequence of characters delimited by the current delimiter as set by the
itemDelimiter property. Counting starts at the beginning of the field. If the mouse pointer is
not over a field, the result is -1.

The value of the mouselItem property can change in a handler or loop. If a handler or loop relies
on the initial value of mouselItem when the handler or loop begins, call this property once and
assign its value to a local variable.

Example

This statement determines whether the pointer is over a field sprite and changes the content of
the field cast member Instructions to “Please point to an item.” when it is not:

-- Lingo syntax
if (mouselItem = -1) then
    member("Instructions").text = "Please point to an item."
end if

// JavaScript syntax
if (_mouselItem == -1) {
    member("Instructions").text = "Please point to an item."
}

This statement assigns the item under the pointer in the specified field to the variable
currentItem:

-- Lingo syntax
currentItem = member(_mouse.mouseMember).item[_mouse.mouselItem]

// JavaScript syntax
var currentItem = member(_mouse.mouseMember).getProp("item",
    _mouse.mouselItem);

See also

itemDelimiter, Mouse, mouseChar, mouseLine, mouseWord
mouseLevel

Usage

-- Lingo syntax
spriteObjRef.mouseLevel

// JavaScript syntax
spriteObjRef.mouseLevel;

Description

QuickTime sprite property; controls how Director passes mouse clicks on a QuickTime sprite
to QuickTime. The ability to pass mouse clicks within the sprite's bounding rectangle can be
useful for interactive media such as QuickTime VR. The mouseLevel sprite property can have
these values:

• #controller—Passes clicks only on the movie controller to QuickTime. Director responds
  only to mouse clicks that occur outside the controller. This is the standard behavior for
  QuickTime sprites other than QuickTime VR.

• #all—Passes all mouse clicks within the sprite's bounding rectangle to QuickTime. No clicks
  pass to other Lingo handlers.

• #none—Does not pass any mouse clicks to QuickTime. Director responds to all mouse clicks.

• #shared—Passes all mouse clicks within a QuickTime VR sprite's bounding rectangle to
  QuickTime and then passes these events to Lingo handlers. This is the default value for
  QuickTime VR.

This property can be tested and set.

Example

This frame script checks to see if the name of the QuickTime sprite in channel 5 contains the
string "QTVR." If it does, this script sets mouseLevel to #all; otherwise, it sets mouseLevel to
#none.

-- Lingo syntax
on prepareFrame
  if sprite(5).member.name contains "QTVR" then
    sprite(5).mouseLevel = #all
  else
    sprite(5).mouseLevel = #none
  end if
end

// JavaScript syntax
function prepareFrame() {
  var nm = sprite(5).member.name;
  var nmStr = nm.indexOf("QTVR");
  if (nmStr != -1) {
    sprite(5).mouseLevel = symbol("all");
  } else {
    sprite(5).mouseLevel = symbol("none");
  }
}
**mouseLine**

**Usage**

--- Lingo syntax

`_mouse.mouseLine`

// JavaScript syntax

`_mouse.mouseLine;`

**Description**

Mouse property; contains the number of the line under the pointer when the property is called and the pointer is over a field sprite. Read-only.

Counting starts at the beginning of the field; a line is defined by Return delimiter, not by the wrapping at the edge of the field. When the mouse pointer is not over a field sprite, the result is -1.

The value of the `mouseLine` property can change in a handler or loop. If a handler or loop uses this property multiple times, it's usually a good idea to call the property once and assign its value to a local variable.

**Example**

This statement determines whether the pointer is over a field sprite and changes the content of the field cast member Instructions to “Please point to a line.” when it is not:

--- Lingo syntax

```lingo
if (_mouse.mouseLine = -1) then
    member("Instructions").text = "Please point to a line."
end if
```

// JavaScript syntax

```javascript
if (_mouse.mouseLine == -1) {
    member("Instructions").text = "Please point to a line.";
}
```

This statement assigns the contents of the line under the pointer in the specified field to the variable `currentLine`:

--- Lingo syntax

```lingo
currentLine = member(_mouse.mouseMember).line[_mouse.mouseLine]
```

// JavaScript syntax

```javascript
var currentLine = member(_mouse.mouseMember).getProp("line", _mouse.mouseLine);
```

**See also**

`Mouse, mouseChar, mouseItem, mouseWord`
mouseLoc

Usage
-- Lingo syntax
_mouse.mouseLoc

// JavaScript syntax
_mouse.mouseLoc;

Description
Mouse property; returns the current position of the mouse as a point(). Read-only.
The point location is given as two coordinates, with the horizontal location first, then the vertical location.

Example
The following statement displays the current position of the mouse.
-- Lingo syntax
trace(_mouse.mouseLoc)

// JavaScript syntax
trace(_mouse.mouseLoc);

See also
Mouse, mouseH, mouseV

mouseMember

Usage
-- Lingo syntax
_mouse.mouseMember

// JavaScript syntax
_mouse.mouseMember;

Description
Mouse property; returns the cast member assigned to the sprite that is under the pointer when the property is called. Read-only.

When the pointer is not over a sprite, this property returns the result VOID (Lingo) or null (JavaScript syntax).

You can use this property to make a movie perform specific actions when the pointer rolls over a sprite and the sprite uses a certain cast member.

The value of the mouseMember property can change frequently. To use this property multiple times in a handler with a consistent value, assign the mouseMember value to a local variable when the handler starts and use the variable.
Example

The following statement checks whether the cast member Off Limits is the cast member assigned to the sprite under the pointer and displays an alert if it is. This example shows how you can specify an action based on the cast member assigned to the sprite.

-- Lingo syntax
if (_mouse.mouseMember = member("Off Limits")) then
   _player.alert("Stay away from there!")
end if

// JavaScript syntax
if (_mouse.mouseMember = member("Off Limits")) {
   _player.alert("Stay away from there!");
}

This statement assigns the cast member of the sprite under the pointer to the variable lastMember:

-- Lingo syntax
lastMember = _mouse.mouseMember

// JavaScript syntax
var lastMember = _mouse.mouseMember;

See also

castLibNum, Mouse

mouseOverButton

Usage

-- Lingo syntax
spriteObjRef.mouseOverButton

// JavaScript syntax
spriteObjRef.mouseOverButton;

Description

Flash sprite property; indicates whether the mouse pointer is over a button in a Flash movie sprite specified by the whichFlashSprite parameter (TRUE), or whether the mouse pointer is outside the bounds of the sprite or the mouse pointer is within the bounds of the sprite but over a nonbutton object, such as the background (FALSE).

This property can be tested but not set.

Example

This frame script checks to see if the mouse pointer is over a navigation button in the Flash movie in sprite 3. If the mouse pointer is over the button, the script updates a text field with an appropriate message; otherwise, the script clears the message.

-- Lingo syntax
on enterFrame
   case sprite(3).mouseOverButton of
      TRUE:
         member("Message Line").text = "Click here to go to the next page."
      FALSE:
         member("Message Line").text = " "
   end case
_movie.updatestage()
end

// JavaScript syntax
function enterFrame() {
    switch(sprite(3).mouseOverButton)
    case 1:
        member("Message Line").text = "Click here to go to the next page."
        break;
    case 0:
        member("Message Line").text = " ";
        break;
    }
    _movie.updatestage();
}

mouseUp

Usage
-- Lingo syntax
_movie.mouseUp

// JavaScript syntax
_movie.mouseUp;

Description
Mouse property; indicates whether the mouse button is released (TRUE) or is being pressed (FALSE). Read-only.

Example
This handler causes the movie to run as long as the user presses the mouse button. The playhead stops when the user releases the mouse button.

-- Lingo syntax
on exitFrame me
    if (_mouse.mouseUp) then
        _movie.go(_movie.frame)
        end if
end if

// JavaScript syntax
function exitFrame() {
    if (_mouse.mouseUp) {
        _movie.go(_movie.frame);
    }
}

This statement instructs Lingo to exit the repeat loop or handler it is in when the user releases the mouse button:

-- Lingo syntax
if (_mouse.mouseUp) then exit

// JavaScript syntax
if (_mouse.mouseUp) {
    return;
}

See also
Mouse, mouseDown, mouseH, mouseV
**mouseUpScript**

**Usage**

the mouseUpScript

**Description**

System property; determines the Lingo that is executed when the mouse button is released. The Lingo is written as a string, surrounded by quotation marks, and can be a simple statement or a calling script for a handler.

When the mouse button is released and the mouseUpScript property is defined, Lingo executes the instructions specified for the mouseUpScript property first. Unless the instructions include the pass command so that the mouseUp message can be passed on to other objects in the movie, no other on mouseUp handlers are executed.

When the instructions you've specified for the mouseUpScript property are no longer appropriate, turn them off by using the statement set the mouseUpScript to empty.

This property can be tested and set. The default value is EMPTY.

**Example**

When this statement is in effect and the movie is paused, the movie always continues whenever the user releases the mouse button:

the mouseUpScript = "go to the frame +1"

With this statement, when the user releases the mouse button after clicking anywhere on the Stage, the movie beeps:

the mouseUpScript = "if the clickOn = 0 then beep"

This statement sets mouseUpScript to the custom handler myCustomHandler. A Lingo custom handler must be enclosed in quotation marks when used with the mouseUpScript property.

the mouseUpScript = "myCustomHandler"

**See also**

stopEvent(), mouseDownScript, on mouseDown (event handler), on mouseUp (event handler)

**mouseV**

**Usage**

-- Lingo syntax
_mouse.mouseV

// JavaScript syntax
_mouse.mouseV;

**Description**

Mouse property; indicates the vertical position of the mouse cursor, in pixels, from the top of the Stage. Read-only.
The value of this property increases as the cursor moves down and decreases as the cursor moves up.

The `mouseV` property is useful for moving sprites to the vertical position of the mouse cursor and checking whether the cursor is within a region of the Stage. Using the `mouseH` and `mouseV` properties together, you can identify the cursor’s exact location.

**Example**

This handler moves sprite 1 to the mouse pointer location and updates the Stage when the user clicks the mouse button:

-- Lingo syntax
on mouseDown
    sprite(1).locH = _mouse.mouseH
    sprite(1).locV = _mouse.mouseV
end

// JavaScript syntax
function mouseDown() {
    sprite(1).locH = _mouse.mouseH;
    sprite(1).locV = _mouse.mouseV;
}

This statement tests whether the pointer is more than 10 pixels above or below a starting point and, if it is, sets the variable `vFar` to `TRUE`:

-- Lingo syntax
startV = 7
if (abs(_mouse.mouseV - startV) > 10) then
    vFar = TRUE
end if

// JavaScript syntax
var startV = 7
if (Math.abs(_mouse.mouseV - startV) > 10) {
    var vFar = true;
}

**See also**

`locH`, `locV`, `Mouse`, `mouseH`, `mouseLoc`

**mouseWord**

**Usage**

-- Lingo syntax
    _mouse.mouseWord

// JavaScript syntax
    _mouse.mouseWord;

**Description**

Mouse property; contains the number of the word under the pointer when the property is called and when the pointer is over a field sprite. Read-only.
Counting starts from the beginning of the field. When the mouse is not over a field, the result is -1.

The value of the mouseWord property can change in a handler or loop. If a handler or loop uses this property multiple times, it's usually a good idea to call the function once and assign its value to a local variable.

Example

This statement determines whether the pointer is over a field sprite and changes the content of the field cast member Instructions to "Please point to a word." when it is not:

```-- Lingo syntax
if (_mouse.mouseWord = -1) then
    member("Instructions").text = "Please point to a word."
else
    member("Instructions").text = "Thank you."
end if
```
```
// JavaScript syntax
if (_mouse.mouseWord == -1) {
    member("Instructions").text = "Please point to a word."
} else {
    member("Instructions").text = "Thank you."
}
```

This statement assigns the number of the word under the pointer in the specified field to the variable currentWord:

```-- Lingo syntax
currentWord = member(_mouse.mouseMember).word[_mouse.mouseWord]
```
```
// JavaScript syntax
var currentWord = member(_mouse.mouseMember).getProp("word",
    _mouse.mouseWord);
```

See also

Mouse, mouseChar, mouseItem

**moveableSprite**

**Usage**

```sprite(whichSprite).moveableSprite```
```
the moveableSprite of sprite whichSprite
```

**Description**

Sprite property; indicates whether a sprite can be moved by the user (TRUE) or not (FALSE).

You can make a sprite moveable by using the Moveable option in the Score. However, to control whether a sprite is moveable and to turn this condition on and off as needed, use Lingo. For example, to let users drag sprites one at a time and then make the sprites unmoveable after they are positioned, turn the moveableSprite sprite property on and off at the appropriate times.

**Note:** For more customized control such as snapping back to the origin or animating while dragging, create a behavior to manage the additional functionality.

This property can be tested and set.
Example

This handler makes sprites in channel 5 moveable:

```lingo
on spriteMove
    sprite(5).moveableSprite = TRUE
end
```

This statement checks whether a sprite is moveable and, if it is not, displays a message:

```lingo
if sprite(13).moveableSprite = FALSE then
    member("Notice").text = "You can't drag this item by using the mouse."
```

See also

mouseLoc

movie

Usage

```lingo
-- Lingo syntax
windowObjRef.movie
```

```javascript
// JavaScript syntax
windowObjRef.movie;
```

Description

Window property; returns a reference to the movie object that is playing in a specified window. Read-only.

Example

This statement displays in the Message window the movie object that is playing in the window named Empires:

```lingo
-- Lingo syntax
trace(window("Empires").movie)
```

```javascript
// JavaScript syntax
trace(window("Empires").movie);
```

See also

Window

multiSound

Usage

```lingo
the multiSound
```

Description

System property; specifies whether the system supports more than one sound channel and requires a Windows computer to have a multichannel sound card (TRUE) or not (FALSE).

Example

This statement plays the sound file Music in sound channel 2 if the computer supports more than one sound channel:

```lingo
if the multiSound then sound playFile 2, "Music.wav"
```
name

Usage

-- Lingo syntax
castObjRef.name
memberObjRef.name
_movie.name
windowObjRef.name

// JavaScript syntax
castObjRef.name;
memberObjRef.name;
_movie.name;
windowObjRef.name;

Description

Cast, Member, Movie, and Window property; returns or sets the name of an object. Read/write for Cast, Member, and Window objects, read-only for Movie objects.

Example

This statement changes the name of the window Yesterday to Today:

-- Lingo syntax
window("Yesterday").name = "Today"

// JavaScript syntax
window("Yesterday").name = "Today";

See also

Cast Library, Member, Movie, Window

name (3D)

Usage

member(whichCastmember).texture(whichTexture).name
member(whichCastmember).shader(whichShader).name
member(whichCastmember).motion(whichMotion).name
member(whichCastmember).modelResource(whichModelResource).name
member(whichCastmember).model(whichModel).name
member(whichCastmember).light(whichLight).name
member(whichCastmember).camera(whichCamera).name
member(whichCastmember).group(whichGroup).name
node.name

Description

3D property; when used with an object reference, allows you to get the name of the referenced object. You can only get the name; the name can't be changed.

All names must be unique. If created through Lingo, the name returned is the name given in the constructor function. If created through a 3D-authoring program the name returned may be the name of the model.

Example

This statement sets the name of the fifth camera in the cast member TableScene to BirdCam:

member("TableScene").camera[5].name = "BirdCam"
name (menu property)

Usage
the name of menu(whichMenu)
the name of menu whichMenu

Description
Menu property; returns a string containing the name of the specified menu number.
This property can be tested but not set. Use the installMenu command to set up a custom menu bar.

Note: Menus are not available in Shockwave Player.

Example
This statement assigns the name of menu number 1 to the variable firstMenu:
firstMenu = menu(1).name

The following handler returns a list of menu names, one per line:
on menuList
   theList = []
   repeat with i = 1 to the number of menus
      theList[i] = the name of menu i
   end repeat
   return theList
end menuList

See also
number (menus), name (menu item property)

name (menu item property)

Syntax
the name of menuItem(whichItem) of menu(whichMenu)
the name of menuItem whichItem of menu whichMenu

Description
Menu property; determines the text that appears in the menu item specified by whichItem in the menu specified by whichMenu. The whichItem argument is either a menu item name or a menu item number; whichMenu is either a menu name or a menu number.

This property can be tested and set.

Note: Menus are not available in Shockwave Player.

Example
This statement sets the variable itemName to the name of the eighth item in the Edit menu:
set itemName = the name of menuItem(8) of menu("Edit")

This statement causes a specific filename to follow the word Open in the File menu:
the name of menuItem("Open") of menu("fileMenu") = "Open" && fileName

See also
name (menu property), number (menu items)
name (Sprite)

Usage
-- Lingo syntax
spriteObjRef.name

// JavaScript syntax
spriteObjRef.name;

Description
Sprite property; identifies the name of a sprite. Read/write during a Score recording session only.
Unlike sprite display properties such as `backColor` and `blend`, a sprite name cannot be a scripted sprite. This means that the name can only be set during a Score recording session—between calls to the Movie object's `beginRecording()` and `endRecording()` methods. You can only set the name if `beginRecording()` is called on or before a frame in the Score that contains the sprite.

Note: Starting a Score recording session using `beginRecording()` resets the properties of all scripted sprites and sprite channels.

If you use script to create a new sprite during a Score recording session and you use `updateFrame()` to apply the sprite data to the session, you cannot set the sprite's name until you go back to the frame in which the sprite was created. Use a method such as `go()` to go back to a specific frame.

Example
This statement sets the name of sprite 5 to Background Sound:

-- Lingo syntax
sprite(5).name = "Background Sound"

// JavaScript syntax
sprite(5).name = "Background Sound";

See also
`beginRecording()`, `endRecording()`, `go()`, `Sprite`, `updateFrame()`

name (Sprite Channel)

Usage
-- Lingo syntax
spriteChannelObjRef.name

// JavaScript syntax
spriteChannelObjRef.name;

Description
Sprite Channel property; identifies the name of a sprite channel. Read/write during a Score recording session only.

Set the name of a sprite channel during a Score recording session—between calls to the Movie object's `beginRecording()` and `endRecording()` methods.

Note: Starting a Score recording session using `beginRecording()` resets the properties of all scripted sprites and sprite channels.
Unlike a Sprite object's name property, which can only be set on or after a frame in which a sprite appears in the Score, a Sprite Channel object's name property can be set on an empty channel. This means that you do not need to call updateFrame() before setting the name of the sprite channel.

A change to a sprite channel's name using script is not reflected in the Score window.

Example

This statement sets the name of sprite channel 6 to Kite String during a Score recording session:

--- Lingo syntax
on mouseDown
_movie.beginRecording()
channel(6).name = "Kite string"
_movie.endRecording()
end

// JavaScript syntax
function mouseDown() {
_movie.beginRecording();
channel(6).name = "Kite string";
_movie.endRecording();
}

See also
beginRecording(), endRecording(), Sprite Channel

name (timeout)

Usage
timeoutObject.name

Description
This timeout property is the name of the timeout object as defined when the object is created. The new() command is used to create timeout objects.

Example

This timeout handler opens an alert with the name of the timeout that sent the event:

on handleTimeout timeoutObject
alert "Timeout:" & timeoutObject.name
end

See also
forget() (Timeout), new(), period, persistent, target, time (timeout object), timeout(), timeoutHandler, timeoutList

name (XML)

Usage
XMLnode.name

Description
XML property; returns the name of the specified XML node.
Example

Beginning with this XML:
```xml
<?xml version="1.0"?>
<e1>
  <tagName attr1="val1" attr2="val2"/>
  <e2>element 2</e2>
  <e3>element 3</e3>
</e1>
```

This Lingo returns the name of the second tag that is nested within the tag `<e1>`:
```
put gParserObject.child[1].child[2].name
```

---

**See also**

`attributeName`

---

### near (fog)

**Usage**

```lingo
member(whichCastmember).camera(whichCamera).fog.near
cameraReference.fog.near
member(whichCastmember).camera(whichCamera).fog.far
cameraReference.fog.far
```

**Description**

3D properties; this property allows you to get or set the distance from the front of the camera to the point where the fogging starts if `fog.enabled` is `TRUE`.

The default value for this property is 0.0.

**Example**

The following statement sets the `near` property of the fog of the camera `Defaultview` to 100. If the fog's `enabled` property is set to `TRUE` and its `decayMode` property is set to `#linear`, fog will first appear 100 world units in front of the camera.
```
member("3d world").camera("defaultview").fog.near = 100.0
```

**See also**

`fog`, `far (fog)`, `enabled (fog)`, `decayMode`

---

### nearFiltering

**Usage**

```lingo
member(whichCastmember).texture(whichTexture).nearFiltering
member(whichCastmember).shader(whichShader).\texture(whichTexture).nearFiltering
member(whichCastmember).model(whichModel).shader.texture(\ whichTexture).nearFiltering
member(whichCastmember).model(whichModel).shaderList[shaderListIndex].texture(whichTexture).nearFiltering
```
Description

3D texture property; allows you to get or set whether bilinear filtering is used when rendering a projected texture map that covers more screen space than the original texture source. Bilinear filtering smooths any errors across the texture and thus improves the texture's appearance. Bilinear filtering smooths errors in two dimensions. Trilinear filtering smooths errors in three dimensions. Filtering improves appearance at the expense of performance, with bilinear being less performance-costly than trilinear.

When the property's value is **TRUE**, bilinear filtering is used. When the value is **FALSE**, bilinear filtering is not used. The default is **TRUE**.

Example

This statement turns off bilinear filtering for the texture named `gbTexture` in the cast member `Scene`:

```lingo
member("Scene").texture("gbTexture").nearFiltering = FALSE
```

**netPresent**

Usage

-- Lingo syntax
_player.netPresent

// JavaScript syntax
_player.netPresent;

Description

Player property; determines whether the Xtra extensions needed to access the Internet are available but does not report whether an Internet connection is currently active. Read-only.

If the Net Support Xtra extensions are not available, `netPresent` will function properly, but `netPresent()` will cause a script error.

Example

This statement sends an alert if the Xtra extensions are not available:

```lingo
-- Lingo syntax
if (not(_player.netPresent)) then
    _player.alert("Sorry, the Network Support Xtras could not be found.")
end if
```

// JavaScript syntax
if (!_player.netPresent) {
    _player.alert("Sorry, the Network Support Xtras could not be found.");
}

See also

Player
netThrottleTicks

Usage
-- Lingo syntax
_player.netThrottleTicks

// JavaScript syntax
_player.netThrottleTicks;

Description
Player property; in the Macintosh authoring environment, allows you to control the frequency of servicing to a network operation. Read/write.

The default value is 15. The higher the value is set, the smoother the movie playback and animation is, but less time is spent servicing any network activity. A low setting allows more time to be spent on network operations, but will adversely affect playback and animation performance.

This property only affects the authoring environment and projectors on the Macintosh. It is ignored on Windows or Shockwave Player on the Mac.

See also
Player

node

Usage
-- Lingo syntax
spriteObjRef.node

// JavaScript syntax
spriteObjRef.node;

Description
QuickTime VR sprite property; the current node ID displayed by the sprite.

This property can be tested and set.

nodeEnterCallback

Usage
-- Lingo syntax
spriteObjRef.nodeEnterCallback

// JavaScript syntax
spriteObjRef.nodeEnterCallback;

Description
QuickTime VR sprite property; contains the name of the handler that runs after the QuickTime VR movie switches to a new active node on the Stage. The message has two arguments: the me parameter and the ID of the node that is being displayed.

The QuickTime VR sprite receives the message first.
To clear the callback, set this property to 0.
To avoid a performance penalty, set a callback property only when necessary. This property can be tested and set.

**nodeExitCallback**

**Usage**

-- Lingo syntax

spriteObjRef.nodeExitCallback

// JavaScript syntax

spriteObjRef.nodeExitCallback;

**Description**

QuickTime VR sprite property; contains the name of the handler that runs when the QuickTime VR movie is about to switch to a new active node on the Stage. The message has three arguments: the `me` parameter, the ID of the node that the movie is about to leave, and the ID of the node that the movie is about to switch to.

The value that the handler returns determines whether the movie goes on to the next node. If the handler returns `#continue`, the QuickTime VR sprite continues with a normal node transition. If the handler returns `#cancel`, the transition doesn’t occur and the movie stays in the original node.

Set this property to 0 to clear the callback.

The QuickTime VR sprite receives the message first.

To avoid a performance penalty, set a callback property only when necessary.

This property can be tested and set.

**nodeType**

**Usage**

-- Lingo syntax

spriteObjRef.nodeType

// JavaScript syntax

spriteObjRef.nodeType;

**Description**

QuickTime VR sprite property; gives the type of node that is currently on the Stage for the specified sprite. Possible values are `#object`, `#panorama`, or `#unknown`. (`#unknown` is the value for a sprite that isn’t a QuickTime VR sprite.)

This property can be tested but not set.
normallist

Usage

member(whichCastmember).modelResource(whichModelResource).\n  normalList
model.meshDeform.mesh[index].normalList

Description

3D property; when used with a model resource whose type is "mesh", this property allows you to get or set the normalList property of the model resource.

The normalList property is a linear list of vectors from which you may specify vertex normals when building the faces of your mesh.

This property must be set to a list of exactly the number of vectors specified in the newMesh() call.

Alternately, the normalList property may be generated for you by the generateNormals() method of mesh model resources.

In the context of the meshDeform modifier, the normalList property is similarly a linear list of vectors from which you may specify vertex normals when deforming your mesh.

For more information on face normals and vertex normals, see the normals entry.

Example

put member(5,2).modelResource("mesh square").normalList
-- [vector(0,0,1)]
member(2).modelResource("mesh3").normalList[2] = vector\n  (205.0000, -300.0000, 27.0000)

See also

face, meshDeform (modifier)

normals

Usage

member(whichCastmember).modelResource(whichModelResource).\n  face[index].normals

Usage

3D face property; for model resources whose type is "mesh" (created using the newMesh command) this property allows you to get and set the list of normal vectors used by the face specified by the index parameter.

Set this property to a linear list of integers corresponding to the index position of each vertex's normal in the model resource's normalList property.

This property must be set to the same length as the face[index].vertices list, or it can be an empty list [].

Do not set any value for this property if you are going to generate normal vectors using the generateNormals() command.

If you make changes to this property, or a use the generateNormals() command, you need to call the build() command in order to rebuild the mesh.
Example
This statement sets the normals property of the fifth face of the model resource named Player to a list of integer values:
member("3D").modelResource("Player").face[5].normals = [2,32,14]

See also
face, normalList, vertices

number (Cast)

Usage
-- Lingo syntax
castObjRef.number

// JavaScript syntax
castObjRef.number;

Description
Cast library property; returns the number of a specified cast library. Read-only.

Example
This repeat loop uses the Message window to display the number of cast members that are in each of the movie's casts:

-- Lingo syntax
repeat with n = 1 to _movie.castLib.count
   put(castLib(n).name && "contains" && castLib(n).member.count && " cast members.")
end repeat

// JavaScript syntax
for (var n=1; n<_movie.castLib.count; n++) {
   put(castLib(n).name + " contains " + castLib(n).member.count + " cast members.")
}

See also
Cast Library

number (characters)

Usage
the number of chars in chunkExpression

Description
Chunk expression; returns a count of the characters in a chunk expression.

Chunk expressions are any character (including spaces and control characters such as tabs and carriage returns), word, item, or line in any container of characters. Containers include field cast members and variables that hold strings, and specified characters, words, items, lines, and ranges in containers.

Note: The count() function provides a more efficient alternative for determining the number of characters in a chunk expression.
Example
This statement displays the number of characters in the string “Macromedia, the Multimedia Company” in the Message window:
put the number of chars in "Macromedia, the Multimedia Company"
The result is 34.
This statement sets the variable charCounter to the number of characters in the word i located in the string Names:
charCounter = the number of chars in member("Names").word[i]
You can accomplish the same thing with text cast members using the syntax:
charCounter = member("Names").word[i].char.count
See also
length(), char...of, count(), number (items), number (lines), number (words)

number (items)

Usage
the number of items in chunkExpression

Description
Chunk expression; returns a count of the items in a chunk expression. An item chunk is any sequence of characters delimited by commas.

Chunk expressions are any character, word, item, or line in any container of characters. Containers include fields (field cast members) and variables that hold strings, and specified characters, words, items, lines, and ranges in containers.

Note: The count() function provides a more efficient alternative for determining the number of items in a chunk expression.

Example
This statement displays the number of items in the string “Macromedia, the Multimedia Company” in the Message window:
put the number of items in "Macromedia, the Multimedia Company"
The result is 2.
This statement sets the variable itemCounter to the number of items in the field Names:
itemCounter = the number of items in member("Names").text
You can accomplish the same thing with text cast members using the syntax:
itemCounter = member("Names").item.count
See also
item...of, count(), number (characters), number (lines), number (words)
number (lines)

Usage

the number of lines in chunkExpression

Description

Chunk expression; returns a count of the lines in a chunk expression. (Lines refers to lines delimited by carriage returns, not lines formed by line wrapping.)

Chunk expressions are any character, word, item, or line in any container of characters. Containers include field cast members and variables that hold strings, and specified characters, words, items, lines, and ranges in containers.

Note: The count() function provides a more efficient alternative for determining the number of lines in a chunk expression.

Example

This statement displays the number of lines in the string “Macromedia, the Multimedia Company” in the Message window:

put the number of lines in "Macromedia, the Multimedia Company"

The result is 1.

This statement sets the variable lineCounter to the number of lines in the field Names:

lineCounter = the number of lines in member("Names").text

You can accomplish the same thing with text cast members with the syntax:

lineCounter = member("Names").line.count

See also

text...of, count(), number (characters), number (items), number (words)

number (Member)

Usage

-- Lingo syntax
memberObjRef.number

// JavaScript syntax
memberObjRef.number;

Description

Member property; indicates the cast library number of a specified cast member. Read-only.

The value of this property is a unique identifier for the cast member that is a single integer describing its location in and position in the cast library.

Example

This statement assigns the cast number of the cast member Power Switch to the variable whichCastMember:

-- Lingo syntax
whichCastMember = member("Power Switch").number
// JavaScript syntax
var whichCastMember = member("Power Switch").number;
This statement assigns the cast member Red Balloon to sprite 1:
-- Lingo syntax
sprite(1).member = member("Red Balloon").number

// JavaScript syntax
sprite(1).member = member("Red Balloon").number;
This verifies that a cast member actually exists before trying to switch the cast member in
the sprite:
-- Lingo syntax
property spriteNum
on mouseUp me
  if (member("Mike's face").number > 0) then
    sprite(spriteNum).member = "Mike's face"
  end if
end

// JavaScript syntax
function mouseUp() {
  if (member("Mike's face").number > 0) {
    sprite(this.spriteNum).member = "Mike's face"
  }
}

See also
castLib(), Member

number (menus)

Usage
the number of menus

Description
Menu property; indicates the number of menus installed in the current movie.
This menu property can be tested but not set. Use the installMenu command to set up a custom
menu bar.

Note: Menus are not available in Shockwave Player.

Example
This statement determines whether any custom menus are installed in the movie and, if no menus
are already installed, installs the menu Menubar:
if the number of menus = 0 then installMenu "Menubar"

This statement displays in the Message window the number of menus that are in the
current movie:
put the number of menus

See also
installMenu, number (menu items)
number (menu items)

Usage
the number of menuItems of menu whichMenu

Description
Menu property; indicates the number of menu items in the custom menu specified by whichMenu. The whichMenu parameter can be a menu name or menu number.

This menu property can be tested but not set. Use the installMenu command to set up a custom menu bar.

Note: Menus are not available in Shockwave Player.

Example
This statement sets the variable fileItems to the number of menu items in the custom File menu:
fileItems = the number of menuItems of menu "File"

This statement sets the variable itemCount to the number of menu items in the custom menu whose menu number is equal to the variable i:
itemCount = the number of menuItems of menu i

See also
installMenu, number (menus)

number (Sprite Channel)

Usage
-- Lingo syntax
spriteChannelObjRef.number

// JavaScript syntax
spriteChannelObjRef.number;

Description
Sprite Channel property; returns the number of a sprite channel. Read-only.

Example
This statement displays in the Message window the number of a named sprite channel:

-- Lingo syntax
put(channel("Kite String").number)

// JavaScript syntax
put(channel("Kite String").number);

See also
Sprite
number (system)

Usage
the number of castLibs

Description
System property; returns the number of casts that are in the current movie.
This property can be tested but not set.

Example
This repeat loop uses the Message window to display the number of cast members that are in each of the movie's casts:

```
repeat with n = 1 to the number of castLibs
  put castLib(n).name && "contains" && the number of members of castLib(n) && "cast members."
end repeat
```

number (words)

Usage
the number of words in chunkExpression

Description
Chunk expression; returns the number of words in the chunk expression specified by chunkExpression.

Chunk expressions are any character, word, item, or line in any container of characters. Containers include field cast members and variables that hold strings, and specified characters, words, items, lines, and ranges in containers.

To accomplish this functionality with text cast members, see count.

Note: The count() function provides a more efficient alternative for determining the number of words in a chunk expression.

Example
This statement displays in the Message window the number of words in the string "Macromedia, the multimedia company":

```
put the number of words in "Macromedia, the multimedia company"
```

The result is 4.

This handler reverses the order of words in the string specified by the argument wordList:

```
on reverse wordList
  theList = EMPTY
  repeat with i = 1 to the number of words in wordList
    put word i of wordList & " " before theList
  end repeat
  delete theList.char[theList.char.count]
  return theList
end
```

See also
count(), number (characters), number (items), number (lines), word...of
number of members

Usage
the number of members of castLib whichCast

Description
Cast member property; indicates the number of the last cast member in the specified cast.
This property can be tested but not set.

Example
The following statement displays in the Message window the type of each cast member in the cast Central Casting. The number of members of castLib property is used to determine how many times the loop repeats.

```
repeat with i = 1 to the number of members of castLib("Central Casting")
    put "Cast member" && i && " is a" && member(i, "Central Casting").type
end repeat
```

number of xtras

Usage
the number of xtras

Description
System property; returns the number of scripting Xtra extensions available to the movie. The Xtra extensions may be either those opened by the openxlib command or those present in the Configuration\Xtras folder.
This property can be tested but not set.

Example
This statement displays in the Message window the number of scripting Xtra extensions that are available to the movie:

```
put the number of xtras
```

numChannels

Usage
-- Lingo syntax
memberObjRef.numChannels

// JavaScript syntax
memberObjRef.numChannels;

Description
Shockwave Audio (SWA) cast member property; returns the number of channels within the specified SWA streaming cast member. The value can be either 1 for monaural or 2 for stereo.
This property is available only after the SWA streaming cast member begins playing or after the file has been preloaded using the preLoadBuffer command.
This property can be tested but not set.
Example

This example assigns the number of sound channels of the SWA streaming cast member Duke Ellington to the field cast member Channel Display:

```-- Lingo syntax
myVariable = member("Duke Ellington").numChannels
if myVariable = 1 then
  member("Channel Display").text = "Mono"
else
  member("Channel Display").text = "Stereo"
end if
```

```// JavaScript syntax
var myVariable = member("Duke Ellington").numChannels;
if (myVariable = 1) {
  member("Channel Display").text = "Mono";
} else {
  member("Channel Display").text = "Stereo";
}
```

numParticles

Usage

```member(whichCastmember).modelResource(whichModelResource).
  emitter.numParticles
modelResourceObjectReference.emitter.numParticles```

Description

3D property; when used with a model resource whose type is #particle, allows you to get or set the numParticles property of the resource's particle emitter. The value must be greater than 0 and no more than 100000. The default setting is 1000.

Example

In this example, ThermoSystem is a model resource of the type #particle. This statement sets the number of particles in ThermoSystem to 50000.

```member("Fires").modelResource("ThermoSystem").emitter.
  numParticles = 50000```

See also

emitter

numSegments

Usage

```member(whichCastmember).modelResource(whichModelResource).
  numSegments```

Description

3D property; when used with a model resource whose type is #cylinder, allows you to get or set the numSegments property of the model resource.

The numSegments property determines the number of segments running from the top cap of the cylinder to the bottom cap. This property must be greater than or equal to the default value of 2.
The smoothness of the cylinder's surface depends upon the value specified for this property. The greater the property value the smoother the cylinder's surface will appear.

Example

This statement sets the numSegments property of the model resource named Cylinder03 to 10:

```lingo
member("3D World").modelResource("Cylinder03").numSegments = 10
```

**obeyScoreRotation**

**Usage**

```lingo
member(flashMember).obeyScoreRotation
```

**Description**

Flash cast member property; set to TRUE or FALSE to determine if a Flash movie sprite uses the rotation information from the Score, or the older rotation property of Flash assets.

This property is automatically set to FALSE for all movies created in Director prior to version 7 in order to preserve old functionality of using the member rotation property for all sprites containing that Flash member.

New assets created in version 7 or later will have this property automatically set to TRUE. If set to TRUE, the rotation property of the member is ignored and the Score rotation settings are obeyed instead.

Example

The following sprite script sets the obeyScoreRotation property of cast member "dalmation" to 1 (TRUE), then rotates the sprite which contains the cast member 180°.

```lingo
on mouseUp me
  member("dalmation").obeyScoreRotation = 1
  sprite(1).rotation = sprite(1).rotation + 180
end
```

This property can be tested and set.

See also

rotation

**optionDown**

**Usage**

```lingo
-- Lingo syntax
_key.optionDown
```

```javascript
// JavaScript syntax
_key.optionDown;
```

**Description**

Key property; determines whether the user is pressing the Alt key (Windows) or the Option key (Macintosh). Read-only.

This property returns TRUE if the user is pressing the Alt or Option key; otherwise, it returns FALSE.
In Windows, `optionDown` does not work in projectors if Alt is pressed without another nonmodifier key. Avoid using `optionDown` if you intend to distribute a movie as a Windows projector and need to detect only the modifier key press; use `controlDown` or `shiftDown` instead.

On the Macintosh, pressing the Option key changes the `key` value, so use `keyCode` instead.

**Example**

This handler checks whether the user is pressing the Alt or the Option key and, if so, calls the handler named `doOptionKey`:

```-- Lingo syntax
on keyDown
    if (_key.optionDown) then
        doOptionKey(_key.key)
    end if
end
```

```// JavaScript syntax
function keyDown() {
    if (_key.optionDown) {
        doOptionKey(_key.key);
    }
}
```

**See also**

`controlDown`, `Key`, `key`, `keyCode`, `shiftDown`

---

**organizationName**

**Usage**

```-- Lingo syntax
_player.organizationName
```

```// JavaScript syntax
_player.organizationName;
```

**Description**

Player property; contains the company name entered during installation of Director. Read-only. This property is available in the authoring environment only. It can be used in a movie in a window tool that is personalized to show the user’s information.

**Example**

The following handler would be located in a movie script of a movie in a window (MIAW). It places the user’s name and serial number into a display field when the window is opened:

```-- Lingo syntax
on prepareMovie
    displayString = _player.userName & RETURN & _player.organizationName & RETURN & _player.serialNumber
    member("User Info").text = displayString
end
```

```// JavaScript syntax
function prepareMovie() {
    var displayString = _player.userName + 
    + _player.organizationName
    + _player.serialNumber;
    member("User Info").text = displayString;
}
See also

Player

originalFont

Usage

-- Lingo syntax
memberObjRef.originalFont

// JavaScript syntax
memberObjRef.originalFont;

Description

Font cast member property; returns the exact name of the original font that was imported when
the given cast member was created.

Example

This statement displays the name of the font that was imported when cast member 11
was created:

-- Lingo syntax
put(member(11).originalFont)

// JavaScript syntax
put(member(11).originalFont);

See also

recordFont, bitmapSizes, characterSet

originH

Usage

-- Lingo syntax
memberOrSpriteObjRef.originH

// JavaScript syntax
memberOrSpriteObjRef.originH;

Description

Cast member and sprite property; controls the horizontal coordinate of a Flash movie or vector
shape's origin point, in pixels. The value can be a floating-point value.

The origin point is the coordinate in a Flash movie or vector shape around which scaling and
rotation occurs. The origin point can be set with floating-point precision using the separate
originH and originV properties, or it can be set with integer precision using the single
originPoint property.

You can set the originH property only if the originMode property is set to #point.

This property can be tested and set. The default value is 0.

Note: This property must be set to the default value if the scaleMode property is set to #autoSize, or
the sprite does not display correctly.
Example

This sprite script uses the `originMode` property to set up a Flash movie sprite so it's origin point can be set to a specific point. It then sets the horizontal and vertical origin points.

-- Lingo syntax
property spriteNum

on beginSprite me
    sprite(spriteNum).originMode = #point
    sprite(spriteNum).originH = 100
    sprite(spriteNum).originV = 80
end

// JavaScript syntax
function beginSprite() {
    sprite(this.spriteNum).originMode = symbol("point");
    sprite(this.spriteNum).originH = 100;
    sprite(this.spriteNum).originV = 80;
}

See also

`originV`, `originMode`, `originPoint`, `scaleMode`

originMode

Usage

-- Lingo syntax
memberOrSpriteObjRef.originMode

// JavaScript syntax
memberOrSpriteObjRef.originMode;

Description

Cast member property and sprite property; sets the origin point around which scaling and rotation occurs, as follows:

• #center (default)—The origin point is at the center of the Flash movie.
• #topLeft—The origin point is at the top left of the Flash movie.
• #point—The origin point is at a point specified by the `originPoint`, `originH`, and `originV` properties.

This property can be tested and set.

Note: This property must be set to the default value if the `scaleMode` property is set to #autoSize, or the sprite will not display correctly.
**Example**

This sprite script uses the `originMode` property to set up a Flash movie sprite so its origin point can be set to a specific point. It then sets the horizontal and vertical origin points.

```-- Lingo syntax
property spriteNum

on beginSprite me
    sprite(spriteNum).originMode = #point
    sprite(spriteNum).originH = 100
    sprite(spriteNum).originV = 80
end

// JavaScript syntax
function beginSprite() {
    sprite(this.spriteNum).originMode = symbol("point");
    sprite(this.spriteNum).originH = 100;
    sprite(this.spriteNum).originV = 80;
}
```

**See also**

`originH`, `originV`, `originPoint`, `scaleMode`

**originPoint**

**Usage**

```-- Lingo syntax
memberOrSpriteObjRef.originPoint

// JavaScript syntax
memberOrSpriteObjRef.originPoint;
```

**Description**

Cast member and sprite property; controls the origin point around which scaling and rotation occurs of a Flash movie or vector shape.

The `originPoint` property is specified as a Director point value: for example, `point(100,200)`. Setting a Flash movie or vector shape's origin point with the `originPoint` property is the same as setting the `originH` and `originV` properties separately. For example, setting the `originPoint` property to `point(50,75)` is the same as setting the `originH` property to 50 and the `originV` property to 75.

Director point values specified for the `originPoint` property are restricted to integers, whereas `originH` and `originV` can be specified with floating-point numbers. When you test the `originPoint` property, the point values are truncated to integers. As a rule of thumb, use the `originH` and `originV` properties for precision; use the `originPoint` property for speed and convenience.

You can set the `originPoint` property only if the `originMode` property is set to `#point`.

This property can be tested and set. The default value is 0.

**Note:** This property must be set to the default value if the `scaleMode` property is set to `#autoSize`, or the sprite will not display correctly.
Example

This sprite script uses the originMode property to set up a Flash movie sprite so its origin point can be set to a specific point. It then sets the origin points.

-- Lingo syntax
property spriteNum

on beginSprite me
    sprite(spriteNum).scaleMode = #showAll
    sprite(spriteNum).originMode = #point
    sprite(spriteNum).originPoint = point(100, 80)
end

// JavaScript syntax
function beginSprite() {
    sprite(this.spriteNum).scaleMode = symbol("showAll");
    sprite(this.spriteNum).originMode = symbol("point");
    sprite(this.spriteNum).originPoint = point(100, 80);
}

See also

originH, originV, scaleMode

originV

Usage

-- Lingo syntax
memberOrSpriteObjRef.originV

// JavaScript syntax
memberOrSpriteObjRef.originV;

Description

Cast member and sprite property; controls the vertical coordinate of a Flash movie or vector shape's origin point around which scaling and rotation occurs, in pixels. The value can be a floating-point value.

The origin point can be set with floating-point precision using the separate originH and originV properties, or it can be set with integer precision using the single originPoint property.

You can set the originV property only if the originMode property is set to #point.

This property can be tested and set. The default value is 0.

Note: This property must be set to the default value if the scaleMode property is set to #autoSize, or the sprite does not display correctly.
Example

This sprite script uses the `originMode` property to set up a Flash movie sprite so its origin point can be set to a specific point. It then sets the horizontal and vertical origin points.

```
-- Lingo syntax
property spriteNum

on beginSprite me
    sprite(spriteNum).scaleMode = #showAll
    sprite(spriteNum).originMode = #point
    sprite(spriteNum).originH = 100
    sprite(spriteNum).originV = 80
end

// JavaScript syntax
function beginSprite() {
    sprite(this.spriteNum).scaleMode = symbol("showAll");
    sprite(this.spriteNum).originMode = symbol("point");
    sprite(this.spriteNum).originH = 100;
    sprite(this.spriteNum).originV = 80;
}
```

See also

`originH`, `originPoint`, `scaleMode`

**orthoHeight**

**Usage**

```
member(whichCastmember).camera(whichCamera).orthoHeight
member(whichCastmember).camera[cameraindex].orthoHeight
sprite(whichSprite).camera.orthoHeight
```

**Description**

3D property; when `camera.projection` is set to `#orthographic`, the value `camera.orthoHeight` gives the number of perpendicular world units that fit vertically in the sprite. World units are the measuring units for the particular 3D world. They are internally consistent but arbitrarily chosen, and they can vary from one 3D world to another.

You do not need to specify the camera index (`whichCamera`) to access the first camera of the sprite.

The default value of this property is 200.0

**Example**

The following statement sets the `orthoHeight` of the camera of sprite 5 to 200. This means 200 world units will fit vertically within the sprite.

```
sprite(5).camera.orthoHeight = 200.0
```

See also

`projection`
overlay

Usage

member(whichCastmember).camera(whichCamera).\noverlay[overlayIndex].property
member(whichCastmember).camera(whichCamera).overlay.count

Description

3D camera property; allows both get and set access to the properties of overlays contained in the camera’s list of overlays to be displayed. When used as overlay.count this property returns the total number of overlays contained in the camera’s list of overlays to be displayed.

Overlays are textures displayed in front of all models appearing in a given camera’s view frustum. The overlays are drawn in the order that they appear in the camera’s overlay list, the first item in the list appears behind all other overlays and the last item in the list in front of all other overlays.

Each overlay in the camera’s list of overlays list has the following properties:

• loc allows you to get or set the specific position of the overlay’s regPoint, relative to the camera rect’s upper left corner.
• source allows you to get or set the texture to use as the source image for the overlay.
• scale allows you to get or set the scale value used by the overlay. The scale determines the magnification of the overlay; this property defaults to a value of 1.0.
• rotation allows you to get or set the rotation, in degrees, of the overlay.
• regPoint allows you to get or set the registration point of the overlay relative to the texture’s upper left corner.
• blend allows you to get or set the blending of the overlay to an integer between 0 and 100, indicating how transparent (0) or opaque (100) the overlay is.

Example

This statement displays the scale property of the third overlay in the sprite camera’s overlay list:

put sprite(5).camera.overlay[3].scale
-- 0.5000

See also

addOverlay, removeOverlay, bevelDepth

pageHeight

Usage

-- Lingo syntax
memberObjRef.pageHeight

// JavaScript syntax
memberObjRef.pageHeight;

Description

Field cast member property; returns the height, in pixels, of the area of the field cast member that is visible on the Stage.

This property can be tested but not set.
Example
This statement returns the height of the visible portion of the field cast member Today’s News:

-- Lingo syntax
trace(member("Today's News").pageHeight)

// JavaScript syntax
trace(member("Today's News").pageHeight);

palette

Usage

-- Lingo syntax
memberObjRef.palette

// JavaScript syntax
memberObjRef.palette;

Description
Cast member property; for bitmap cast members only, determines which palette is associated with the cast member specified by whichCastMember.
This property can be tested and set.

Example
This statement displays the palette assigned to the cast member Leaves in the Message window:

-- Lingo syntax
put(member("Leaves").palette)

// JavaScript syntax
put(member("Leaves").palette);

paletteMapping

Usage

-- Lingo syntax
_movie.paletteMapping

// JavaScript syntax
_movie.paletteMapping;

Description
Movie property; determines whether the movie remaps (TRUE) or does not remap (FALSE, default) palettes for cast members whose palettes are different from the current movie palette.
Read/write.

The effect of this property is similar to that of the Remap Palettes When Needed check box in the Movie Properties dialog box.

To display different bitmaps with different palettes simultaneously, set paletteMapping to TRUE. Director looks at each onscreen cast member’s reference palette (the palette assigned in its Cast Member Properties dialog box) and, if it is different from the current palette, finds the closest match for each pixel in the new palette.
The colors of the nonmatching bitmap will be close to the original colors. Remapping consumes processor time, and it's usually better to adjust the bitmap's palette in advance.

Remapping can also produce undesirable results. If the palette changes in the middle of a sprite span, the bitmap immediately remaps to the new palette and appears in the wrong colors. However, if anything refreshes the screen—a transition or a sprite moving across the Stage—then the affected rectangle on the screen appears in remapped colors.

Example

This statement tells the movie to remap the movie's palette whenever necessary:

```
-- Lingo syntax
_movie.paletteMapping = TRUE

// JavaScript syntax
_movie.paletteMapping = true;
```

See also

Movie

**paletteRef**

**Usage**

```
member(whichCastMember).paletteRef
```

**Description**

Bitmap cast member property; determines the palette associated with a bitmap cast member. Built-in Director palettes are indicated by symbols (#systemMac, #rainbow, and so on). Palettes that are cast members are treated as cast member references. This behavior differs from that of the palette member property, which returns a positive number for cast palettes and negative numbers for built-in Director palettes.

This property can be tested and set.

Example

This statement assigns the Macintosh system palette to the bitmap cast member Shell:

```
member("Shell").paletteRef = #systemMac
```

**pan**

**Usage**

```
-- Lingo syntax
soundChannelObjRef.pan

// JavaScript syntax
soundChannelObjRef.pan;
```

**Description**

Sound Channel property; indicates the left/right balance of the sound playing in a sound channel. Read/write.
The range of values is from -100 to 100. -100 indicates only the left channel is heard. 100 indicate only the right channel is being heard. A value of 0 indicates even left/right balance, causing the sound source to appear to be centered. For mono sounds, pan affects which speaker (left or right) the sound plays through.

You can change the pan of a sound object at any time, but if the sound channel is currently performing a fade, the new pan setting doesn't take effect until the fade is complete.

To see an example of pan used in a completed movie, see the Sound Control movie in the Learning/Lingo Examples folder inside the Director application folder.

Example

These statements pan the sound in sound channel 2 from the left channel to the right channel:

```-- Lingo syntax
repeat with x = -100 to 100
    sound(2).pan = x
end repeat

// JavaScript syntax
for (var x = -100; x <= 100; x++) {
    sound(2).pan = x;
}
```

See also

Sound Channel

pan (QTVR property)

Usage

```-- Lingo syntax
spriteObjRef.pan

// JavaScript syntax
spriteObjRef.pan;
```

Description

QuickTime VR sprite property; the current pan of the QuickTime VR movie. The value is in degrees.

This property can be tested and set.

paragraph

Usage

```chunkExpression.paragraph[whichParagraph]
chunkExpression.paragraph[firstParagraph..lastParagraph]
```

Description

Text cast member property; this chunk expression allows access to different paragraphs within a text cast member.

The paragraph is delimited by a carriage return.

```put member("AnimText").paragraph[3]```
See also

parent

Usage

member(whichCastmember).model(whichModel).parent
member(whichCastmember).camera(whichCamera).parent
member(whichCastmember).light(whichLight).parent
member(whichCastmember).group(whichGroup).parent

Description

3D property; when used with a model, camera, light or group reference, this property allows you
to get or set the parent node of the referenced object. The parent node can be any other model,
camera, light or group object.

An object’s transform property defines its scale, position and orientation relative to its
parent object.

Setting an object’s parent property to VOID is the same as removing the object from the world
using the removeFromWorld() command.

Setting an object’s parent property to the World group object (group("World")) is the same as
adding an object to the world using the addToWorld() command.

You can also alter the value of this property by using the addChild command.

Example

The following statement sets the parent property of the model named Tire. Its parent is set to the
model named Car.

member("Scene").model("Tire").parent = \
member("Scene").model("Car")

See also

child (3D), addChild

password

Usage

-- Lingo syntax
memberOrSpriteObjRef.password

// JavaScript syntax
memberOrSpriteObjRef.password;

Description

RealMedia sprite and cast member property; allows you to set the password required to access a
protected RealMedia stream. For security reasons, you cannot use this property to retrieve a
password previously specified for this property. If a password has been set previously, the value of
this property is the string "********". If no password has been set, the value of this property is
an empty string.
Example

The following examples show that the password has been set for the RealMedia stream in the cast member Real or sprite 2.

-- Lingo syntax
put(sprite(2).password) -- "********"
put(member("Real").password) -- "********"

// JavaScript syntax
put(sprite(2).password); // "********"
put(member("Real").password); // "********"

The following examples show that the password has never been set for the RealMedia stream in the cast member Real or sprite 2.

-- Lingo syntax
put(sprite(2).password) -- ""
put(member("Real").password) -- ""

// JavaScript syntax
put(sprite(2).password); // ""
put(member("Real").password); // ""

The following examples set the password for the RealMedia stream in sprite 2 and the cast member Real to "abracadabra".

-- Lingo syntax
sprite(2).password = "abracadabra"
member("Real").password = "abracadabra"

// JavaScript syntax
sprite(2).password = "abracadabra";
member("Real").password = "abracadabra";

See also

userName (RealMedia)

path (Movie)

Usage

-- Lingo syntax
_movie.path

// JavaScript syntax
_movie.path;

Description

Movie property; indicates the pathname of the folder in which the current movie is located.
Read-only.

For pathnames that work on both Windows and Macintosh computers, use the @pathname operator.

To see an example of path used in a completed movie, see the Read and Write Text movie in the Learning/Lingo Examples folder inside the Director application folder.
Example

This statement displays the pathname for the folder containing the current movie:

```-- Lingo syntax
trace(_movie.path)
```

```// JavaScript syntax
trace(_movie.path);
```

This statement plays the sound file Crash.aif stored in the Sounds subfolder of the current movie's folder:

```-- Lingo syntax
sound(1).playFile(_movie.path & "Sounds\Crash.aif")
```

```// JavaScript syntax
sound(1).playFile(_movie.path + "Sounds\Crash.aif");
```

See also

Movie

path (3D)

Usage

```member(whichCastmember).modelResource(whichModelResource).emitter.path```

Description

3D property; when used with a model resource whose type is #particle, allows you to get or set the path property of the resource's particle emitter.

This property is a list of vectors that define the path particles follow over their lifetime. The default value of this property is an empty list `[]`.

Example

In this example, ThermoSystem is a model resource of the type #particle. This statement specifies that the particles of ThermoSystem will follow the path outlined by the list of vectors.

```member("Fires").modelResource("ThermoSystem").emitter.path = \ [vector(0,0,0), vector(15,0,0), vector(30,30,-10)]```

See also

pathStrength, emitter

pathName (Flash member)

Usage

```member(whichFlashMember).pathName```

Description

Cast member property; controls the location of an external file that stores the assets of a Flash movie cast member are stored. You can link a Flash movie to any path on a local or network drive or to a URL.
Setting the path of an unlinked cast member converts it to a linked cast member. This property can be tested and set. The pathName property of an unlinked member is an empty string.

This property is the same as the fileName property for other member types, and you can use fileName instead of pathName.

Example

The following startMovie script creates a new Flash cast member using the new command, sets the newly created cast member's linked property so that the cast member's assets are stored in an external file, and then sets the cast member's pathName property to the location of a Flash movie on the World Wide Web:

```ActionScript
on startMovie
    member(new(#flash)).pathName = "http://www.someURL.com/myFlash.swf"
end
```

See also

fileName (Member), linked

pathStrength

Usage

```
member(whichCastmember).modelResource(whichModelResource).
    emitter.pathStrength
```

Description

3D property; when used with a model resource whose type is #particle, determines how closely the particles follow the path specified by the path property of the emitter. Its range starts at 0.0 (no strength - so the particles won't be attracted to the path) and continues to infinity. Its default value is 0.1. Setting pathStrength to 0.0 is useful for turning the path off temporarily.

As the value of pathStrength gets larger, the entire particle system will get more and more stiff. Large pathStrength values will tend to make the particles bounce around very quickly, unless some dampening force is also used, such as the particle drag property.

This property can be tested and set.

Example

In this example, ThermoSystem is a model resource of the type #particle. This statement sets the pathStrength property of ThermoSystem to 0.97. If a path is outlined by ThermoSystem's emitter.path property, the particles follow that path very closely.

```
member("Fires").modelResource("ThermoSystem").emitter.
    pathStrength = 0.97
```

See also

path (3D), emitter
pattern

**Usage**

```plaintext
member(whichCastMember).pattern
the pattern of member whichCastMember
```

**Description**

Cast member property; determines the pattern associated with the specified shape. Possible values are the numbers that correspond to the swatches in the Tools window's patterns palette. If the shape cast member is unfilled, the pattern is applied to the cast member's outer edge.

This property can be useful in movies with Shockwave content to change images by changing the tiling applied to a shape, allowing you to save memory required by larger bitmaps.

This property can be tested and set.

**Example**

The following statements make the shape cast member Target Area a filled shape and assign it pattern 1, which is a solid color:

```plaintext
member("Target Area").filled = TRUE
member("Target Area").pattern = 1
```

This handler cycles through eight tiles, with each tile's number offset from the previous one, enabling you to create animation using smaller bitmaps:

```plaintext
on exitFrame
  currentPat = member("Background Shape").pattern
  nextPat = 57 + ((currentPat - 56) mod 8)
  member("Background Shape").pattern = nextPat
go the frame
end
```

pausedAtStart (Flash, Digital video)

**Usage**

```plaintext
member(whichFlashOrDigitalVideoMember).pausedAtStart
the pausedAtStart of member whichFlashOrDigitalVideoMember
```

**Description**

Cast member property; controls whether the digital video or Flash movie plays when it appears on the Stage. If this property is `TRUE`, the digital video or Flash movie does not play when it appears. If this property is `FALSE`, it plays immediately when it appears.

For a digital video cast member, the property specifies whether the Paused at Start check box in the Digital Video Cast Member Properties dialog box is selected or not.

This property can be tested and set.

**Example**

This statement turns on the Paused at Start check box in the Digital Video Cast Member Info dialog box for the QuickTime movie Rotating Chair:

```plaintext
member("Rotating Chair").pausedAtStart = TRUE
```
pausedAtStart (RealMedia, Windows Media)

Usage

-- Lingo syntax
memberOrSpriteObjRef.pausedAtStart

// JavaScript syntax
memberOrSpriteObjRef.pausedAtStart;

Description

RealMedia and Windows Media sprite or cast member property; allows you to get or set whether a RealMedia or Windows Media stream on the Stage automatically begins to play when buffering is complete (FALSE or 0) or remains paused (TRUE or 1). Read/write.

This property can be set to an expression that evaluates to TRUE or FALSE. Integer values other than 1 or 0 are treated as TRUE. The default setting for this property is FALSE. You can set this property to TRUE by selecting Paused in the graphical view of the Property inspector.

If this property is set to FALSE, the user must click the Play button in the RealMedia or Windows Media viewer (or a button you have created for this purpose in your movie), or you must call the play() method to play the sprite when buffering is complete.

This property only affects score-based playback and does not affect playback in the RealMedia or Windows Media viewer.

Example

The following examples show that the pausedAtStart property of sprite 2 and the cast member Real is set to FALSE, which means that the RealMedia stream will automatically begin to play once buffering is complete.

-- Lingo syntax
put(sprite(2).pausedAtStart) -- 0
put(member("Real").pausedAtStart) -- 0

// JavaScript syntax
put(sprite(2).pausedAtStart); // 0
put(member("Real").pausedAtStart); // 0

The following examples set the pausedAtStart property for sprite 2 and the cast member Real to TRUE, which means the RealMedia stream will not begin to play unless the play command is called.

-- Lingo syntax
sprite(2).pausedAtStart = TRUE
member("Real").pausedAtStart = TRUE

// JavaScript syntax
sprite(2).pausedAtStart = 1;
member("Real").pausedAtStart = 1;
The following example uses the `pausedAtStart` property to buffer a RealMedia sprite off the Stage, and then play it on the Stage once the buffering is complete. In this example, the RealMedia member has its `pausedAtStart` property set to `TRUE`. An instance of this member is positioned off the Stage, in sprite channel 1. The following frame script should be placed in the sprite span:

```-- Lingo syntax
on exitFrame me
    if sprite(1).state > 3 then -- check to see if buffering is complete
        sprite(1).locH = 162
        sprite(1).locV = 118
        sprite(1).play() -- position and play the sprite
    end if
end
```
```
// JavaScript syntax
function exitFrame() {
    var st = sprite(1).state;
    if (st > 3) { // check to see if buffering is complete
        sprite(1).locH = 162;
        sprite(1).locV = 118;
        sprite(1).play(); // position and play the sprite
    }
}
```

The RealMedia sprite will buffer off the Stage and then appear on the Stage and play immediately when the buffering is complete.

**percentBuffered**

**Usage**

```-- Lingo syntax
memberOrSpriteObjRef.percentBuffered
```
```
// JavaScript syntax
memberOrSpriteObjRef.percentBuffered;
```

**Description**

RealMedia sprite or cast member property; returns the percentage of the buffer that has been filled with the RealMedia stream that is loading from a local file or the server. When this property reaches 100, the buffer is full, and the RealMedia stream begins to play if the `pausedAtStart` property is not set to `TRUE`. This property is dynamic during playback and cannot be set. The buffer is a type of memory cache that contains the portion of the movie that is about to play, usually just a few seconds. The stream enters the buffer as it streams to RealPlayer and leaves the buffer as RealPlayer plays the clip. The buffer allows viewers to view content without downloading the entire file, and prevents network congestion or lapses in bandwidth availability from disrupting the playback stream.

The buffering process is initiated by the `play` command, and once the buffer is full (100%), the portion of the stream that is in the buffer begins to play. Because the initial buffering process takes a few seconds, there is a delay between the time when the `play` command is called and when the stream actually begins to play. You can work around this using the `pausedAtStart` command, starting to play the stream off the Stage during the buffering process, and then displaying the stream on the Stage as it actually begins to play. (For more information, see the example in the `pausedAtStart (RealMedia, Windows Media)` on page 906 entry.)
Example

The following examples show that 56% of the RealMedia stream in sprite 2 and the cast member Real has been buffered.

-- Lingo syntax
put(sprite(2).percentBuffered) -- 56
put(member("Real").percentBuffered) -- 56

// JavaScript syntax
put(sprite(2).percentBuffered); // 56
put(member("Real").percentBuffered); // 56

See also

mediaStatus (RealMedia, Windows Media), pausedAtStart (RealMedia, Windows Media), state (RealMedia)

percentPlayed

Usage

member(whichCastMember).percentPlayed

the percentPlayed of member whichCastMember

Description

Shockwave Audio (SWA) cast member property; returns the percentage of the specified SWA file that has actually played.

This property can be tested only after the SWA sound starts playing or has been preloaded by means of the preloadBuffer command. This property cannot be set.

Example

This handler displays the percentage of the SWA streaming cast member Frank Sinatra that has played and puts the value in the field cast member Percent Played:

on exitFrame
  whatState = member("Frank Sinatra").state
  if whatState > 1 AND whatState < 9 then
    member("Percent Played").text = /
    string(member("Frank Sinatra").percentPlayed)
  end if
end

See also

percentStreamed (Member)

percentStreamed (3D)

Usage

member(whichCastMember).percentStreamed

Description

3D property; allows you to get the percentage of a 3D cast member that has been streamed. This property refers to either the initial file import or to the last file load requested. The value returned is an integer and has a range from 0 to 100. There is no default value for this property.
Example

This statement shows that the cast member PartyScene has finished loading.

```lingo
put member("PartyScene").percentStreamed == 100
```

percentStreamed (Member)

Usage

```Lingo syntax
memberOrSpriteObjRef.percentStreamed
```

```JavaScript syntax
memberOrSpriteObjRef.percentStreamed;
```

Description

Shockwave Audio (SWA) and Flash cast member property, and QuickTime sprite property.

For SWA streaming sounds, gets the percent of a SWA file already streamed from an HTTP or FTP server. For SWA, this property differs from the `percentPlayed` property in that it includes the amount of the file that has been buffered but not yet played. This property can be tested only after the SWA sound starts playing or has been preloaded by means of the `preLoadBuffer` command.

For Flash movie cast members, this property gets the percent of a Flash movie that has streamed into memory.

For QuickTime sprites, this property gets the percent of the QuickTime file that has played.

This property can have a value from 0 to 100%. For a file on a local disk, the value is 100. For files being streamed from the Internet, the `percentStreamed` value increases as more bytes are received. This property cannot be set.

Example

This example displays the percentage of the SWA streaming cast member Ray Charles that has streamed and puts the value in a field:

```Lingo syntax
on exitFrame
  whatState = member("Ray Charles").state
  if whatState > 1 AND whatState < 9 then
    member("Percent Streamed Displayer").text = "%.0f%%"
    string(member("Ray Charles").percentStreamed)
  end if
end
```

```JavaScript syntax
function exitFrame() {
  var whatState = member("Ray Charles").state;
  var pcStm = new String(member("Ray Charles").percentStreamed);
  if (whatState > 1 && whatState < 9) {
    member("Percent Streamed Displayer").text = pcStm;
  }
}
```
This frame script keeps the playhead looping in the current frame so long as less than 60 percent of a Flash movie called Splash Screen has streamed into memory:

```-- Lingo syntax
on exitFrame
  if member("Splash Screen").percentStreamed < 60 then
    _movie.go(_movie.frame)
  end if
end
// JavaScript syntax
function exitFrame() {
  var ssStrm = member("Splash Screen").percentStreamed;
  if (ssStrm < 60) {
    _movie.go(_movie.frame);
  }
}
```

See also
percentPlayed

period

Usage
timeoutObject.period

Description
Object property; the number of milliseconds between timeout events sent by the timeoutObject to the timeout handler.

This property can be tested and set.

Example
This timeout handler decreases the timeout's period by one second each time it's invoked, until a minimum period of 2 seconds (2000 milliseconds) is reached:

```on handleTimeout timeoutObject
  if timeoutObject.period > 2000 then
    timeoutObject.period = timeoutObject.period - 1000
  end if
end handleTimeout
```

See also
name (timeout). persistent. target. time (timeout object). timeout(). timeoutHandler. timeoutList

persistent

Usage
timeoutObject.persistent

Description
Object property; determines whether the given timeoutObject is removed from the timeoutList when the current movie stops playing. If TRUE, timeoutObject remains active. If FALSE, the timeout object is deleted when the movie stops playing. The default value is FALSE.
Setting this property to `TRUE` allows a timeout object to continue generating timeout events in other movies. This is useful when one movie branches to another with the `go to movie` command.

**Example**

This `prepareMovie` handler creates a timeout object that will remain active after the declaring movie stops playing:

```lingo
on prepareMovie
  -- Make a timeout object that sends an event every 60 minutes.
  timeout("reminder").new(1000 * 60 * 60, #handleReminder)
  timeout("reminder").persistent = TRUE
end
```

**See also**

`name (timeout)`, `period`, `target`, `time (timeout object)`, `timeout()`, `timeoutHandler`, `timeoutList`

---

**picture (Member)**

**Usage**

```lingo
-- Lingo syntax
memberObjRef.picture

// JavaScript syntax
memberObjRef.picture;
```

**Description**

Cast member property; determines which image is associated with a bitmap, text, or PICT cast member. To update changes to a cast member's registration point or update changes to an image after relinking it using the `fileName` property, use the following statement:

```lingo
member(whichCastMember).picture = member(whichCastMember).picture
```

where you replace `whichCastMember` with the name or number of the affected cast member.

Because changes to cast members are stored in RAM, this property is best used during authoring. Avoid setting it in projectors.

The property can be tested and set.

**Example**

This statement sets the variable named `pictHolder` to the image in the cast member named Sunset:

```lingo
-- Lingo syntax
pictHolder = member("Sunset").picture

// JavaScript syntax
var pictHolder = member("Sunset").picture;
```

**See also**

picture (Window)

Usage

-- Lingo syntax
windowObjRef.picture

// JavaScript syntax
windowObjRef.picture;

Description

Window property; provides a way to get a picture of the current contents of a window—either the Stage window or a movie in a window (MIAW). Read-only.

You can apply the resulting bitmap data to an existing bitmap or use it to create a new one.

If no picture exists, this property returns VOID (Lingo) or null (JavaScript syntax).

Example

This statement grabs the current content of the Stage and places it into a bitmap cast member:

-- Lingo syntax
member("Stage image").picture = _movie.stage.picture

// JavaScript syntax
member("Stage image").picture = _movie.stage.picture;

See also

Window

platform

Usage

the platform

Description

System property; indicates the platform type for which the projector was created.

This property can be tested but not set.

Possible values are the following:

<table>
<thead>
<tr>
<th>Possible value</th>
<th>Corresponding platform</th>
</tr>
</thead>
<tbody>
<tr>
<td>Macintosh,PowerPC</td>
<td>PowerPC Macintosh</td>
</tr>
<tr>
<td>Windows,32</td>
<td>Windows 95 or Windows NT</td>
</tr>
</tbody>
</table>

For forward compatibility and to allow for addition of values, it is better to test the platform by using contains.
Example

This statement checks whether a projector was created for Windows 95 or Windows NT:

```
on exitFrame
  if the platform contains "Windows,32" then
    castLib("Win95 Art").name = "Interface"
  end if
end
```

See also

runMode

playBackMode

Usage

-- Lingo syntax
memberOrSpriteObjRef.playBackMode

// JavaScript syntax
memberOrSpriteObjRef.playBackMode;

Description

Cast member and sprite property; controls the tempo of a Flash movie or animated GIF cast member with the following values:

- **#normal (default)**—Plays the Flash movie or GIF file as close to the original tempo as possible.
- **#lockStep**—Plays the Flash movie or GIF file frame for frame with the Director movie.
- **#fixed**—Plays the Flash movie or GIF file at the rate specified by the fixedRate property.

This property can be tested and set.

Example

This sprite script sets the frame rate of a Flash movie sprite to match the frame rate of the Director movie:

```
-- Lingo syntax
property spriteNum
on beginSprite(me)
  sprite(spriteNum).playBackMode = #lockStep
end

// JavaScript syntax
function beginSprite() {
  sprite(this.spriteNum).playBackMode = symbol("lockStep");
}
```

See also

fixedRate
Playing

Usage
-- Lingo syntax
spriteObjRef.playing

// JavaScript syntax
spriteObjRef.playing;

Description
Flash sprite property; indicates whether a Flash movie is playing (TRUE) or stopped (FALSE).
This property can be tested but not set.

Example
This frame script checks to see if the Flash movie sprite in channel 5 is playing and, if it is not,
starts the movie:
-- Lingo syntax
on enterFrame
  if not sprite(5).playing then
    sprite(5).play()
  end if
end

// JavaScript syntax
function enterFrame() {
  var plg = sprite(5).playing;
  if (plg = 0) {
    sprite(5).play();
  }
}

Playing (3D)

Usage
member(whichCastmember).model(whichModel).keyframePlayer.playing
member(whichCastmember).model(whichModel).bonesPlayer.playing

Description
3D #keyframePlayer and #bonesPlayer modifier property; indicates whether the modifier's
animation playback engine is running (TRUE) or if it's paused (FALSE).
This property can be tested but not set.

Example
This statement shows that the #keyframePlayer animation playback engine for the model
named Alien3 is currently running.
put member("newaliens").model("Alien3").keyframePlayer.playing
-- 1

See also
play() (3D), pause() (3D), playlist, queue() (3D)
playlist

Usage
member(whichCastmember).model(whichModel).keyframePlayer.playlist
member(whichCastmember).model(whichModel).bonesPlayer.playlist

Description
3D #keyframePlayer and #bonesPlayer modifier property; returns a linear list of property lists, each representing a motion queued for playback by the modifier.

Each property list will have the following properties:
• #name is the name of the motion to be played.
• #loop indicates whether the motion's playback should be looped.
• #startTime is the time, in milliseconds at which playback of the animation should begin.
• #endTime is the time, in milliseconds at which playback of the animation ends or when the motion should be looped. A negative value indicates that the motion should be played to the end.
• #scale is rate of play for the motion that is to be multiplied by the modifier's playRate property to determine the actual speed of the motion's playback.

The playlist property can be tested but not set. Use the queue(), play(), playNext(), and removeLast() commands to manipulate it.

Example
The following statement displays the currently queued motions for the model Stroller in the Message window. There are two currently queued motions: Walk and Jump.

```lisp
put member("ParkScene").model("Stroller").bonesPlayer.playlist
-- [[#name: "Walk", #loop: 1, #startTime: 1500, #endTime: 16000, #scale:1.0000, #offset: 0], [#name: "Jump", #loop: 1, #startTime: 0, #endTime: 1200, #scale: 1.0000, #offset: 0]]
```

See also
play() (3D), playNext() (3D), removeLast(), queue() (3D)

playRate (3D)

Usage
member(whichCastmember).model(whichModel).bonesPlayer.playRate
member(whichCastmember).model(whichModel).keyframePlayer.playRate

Description
3D #keyframePlayer and #bonesPlayer modifier property; scale multiplier for the local time of motions being played. This property only partially determines the speed at which motions are executed by the model.

The playback of a motion by a model is the result of either a play() or queue() command. The scale parameter of the play() or queue() command is multiplied by the modifier's playRate property, and the resulting value is the speed at which the particular motion will be played back.
Example

This statement sets the `playRate` property of the `keyframePlayer` modifier for the model named GreenAlien to 3:

```
member("newAliens").model("GreenAlien").keyframePlayer.playRate = 3
```

See also

`play()` (3D), `queue()` (3D), `playlist`, `currentTime` (3D)

**playRate (DVD)**

**Usage**

```
-- Lingo syntax
dvdObjRef.playRate

// JavaScript syntax
dvdObjRef.playRate;
```

**Description**

DVD property; specifies the rate at which a DVD plays forward or backward from the current location. Read/write.

A negative value plays the DVD backward, and a positive value plays the DVD forward.

See also

`DVD`

**playRate (QuickTime, AVI)**

**Usage**

```
-- Lingo syntax
spriteObjRef.playRate

// JavaScript syntax
spriteObjRef.playRate;
```

**Description**

Digital video sprite property; controls the rate at which a digital video in a specific channel plays. The movie rate is a value specifying the playback of the digital video. A value of 1 specifies normal forward play, -1 specifies reverse, and 0 specifies stop. Higher and lower values are possible. For example, a value of 0.5 causes the digital video to play slower than normal. However, frames may be dropped when the `playRate` sprite property exceeds 1. The severity of frame dropping depends on factors such as the performance of the computer the movie is playing on and whether the digital video sprite is stretched.

This property can be tested and set.
Example

This statement sets the rate for a digital video in sprite channel 9 to normal playback speed:

-- Lingo syntax
sprite(9).playRate = 1

// JavaScript syntax
sprite(9).playRate = 1;

This statement causes the digital video in sprite channel 9 to play in reverse:

-- Lingo syntax
sprite(9).playRate = -1

// JavaScript syntax
sprite(9).playRate = -1;

See also
duration (Member), currentTime (QuickTime, AVI)

playRate (Windows Media)

Usage

-- Lingo syntax
windowsMediaObjRef.playRate

// JavaScript syntax
windowsMediaObjRef.playRate;

Description

Windows Media property. Determines the playback rate of a Windows Media cast member.
Read/write.

Example

This statement displays in the Message window the playback rate of cast member 10:

-- Lingo syntax
trace(member(10).playRate)

// JavaScript syntax
trace(member(10).playRate);

See also

Windows Media
pointAtOrientation

Usage

member(whichCastmember).model(whichModel).pointAtOrientation
member(whichCastmember).group(whichGroup).pointAtOrientation
member(whichCastmember).light(whichLight).pointAtOrientation
member(whichCastmember).camera(whichCamera).pointAtOrientation

Description

3D model, light, group and camera property; allows you to get or set how the referenced object responds to the pointAt command. This property is a linear list of two object-relative vectors, the first vector in the list defines which direction is considered the object's front direction, the second defines which direction is considered the object's up direction.

The object's front and up directions do not need to be perpendicular to each other, but they should not be parallel to each other.

Example

This statement displays the object-relative front direction and up direction vectors of the model named bip01:

put member("scene").model("bip01").pointAtOrientation
-- [vector(0.0000, 0.0000, 1.0000), vector(0.0000, 1.0000, 0.0000)]

See also

pointAt

pointOfContact

Usage

collisionData.pointOfContact

Description

3D collisionData property; returns a vector describing the point of contact in a collision between two models.

The collisionData object is sent as an argument with the #collideWith and #collideAny events to the handler specified in the registerForEvent, registerScript, and setCollisionCallback commands.

The #collideWith and #collideAny events are sent when a collision occurs between models to which collision modifiers have been added. The resolve property of the models' modifiers must be set to TRUE.

This property can be tested but not set.
Example

This example has two parts. The first part is the first line of code, which registers the #explode handler for the #collideAny event. The second part is the #explode handler. When two models in the cast member MyScene collide, the #explode handler is called and the collisionData argument is sent to it. The first nine lines of the #explode handler create the model resource named SparkSource and set its properties. This model resource is a single burst of particles. The tenth line of the handler creates a model named SparksModel using the model resource named SparkSource. The last line of the handler sets the position of SparksModel to the position where the collision occurred. The overall effect is a burst of sparks caused by a collision.

member("MyScene").registerForEvent(#collideAny, #explode, 0)

on explode me, collisionData
    nmr = member("MyScene").newModelResource("SparkSource", #particle)
    nmr.emitter.mode = #burst
    nmr.emitter.loop = 0
    nmr.emitter.minSpeed = 30
    nmr.emitter.maxSpeed = 50
    nmr.emitter.direction = vector(0, 0, 1)
    nmr.colorRange.start = rgb(0, 0, 255)
    nmr.colorRange.end = rgb(255, 0, 0)
    nmr.lifetime = 5000
    nm = member("MyScene").newModel("SparksModel", nmr)
    nm.transform.position = collisionData.pointOfContact
end

See also
modelA, modelB

position (transform)

Usage

member(whichCastmember).node(whichNode).transform.position
member(whichCastmember).node(whichNode).getWorldTransform().
    position
transform.position

Description

3D property; allows you to get or set the positional component of a transform. A transform defines a scale, position and rotation within a given frame of reference. The default value of this property is vector(0,0,0).

A node can be a camera, group, light or model object. Setting the position of a node’s transform defines that object’s position within the transform’s frame of reference. Setting the position property of an object’s world relative transform using getWorldTransform().position defines the object’s position relative to the world origin. Setting the position property of an object’s parent relative transform using transform.position defines the object’s position relative to its parent node.

The worldPosition property of a model, light, camera or group object is a shortcut to the getWorldTransform().position version of this property for that object.
Example

The following statement displays the parent-relative position of the model named Tire.
```
put member("scene").model("Tire").transform.position
-- vector(-15.000, -2.5000, 20.0000)
```

The following statement displays the world-relative position of the model named Tire.
```
put member("scene").model("Tire").getWorldTransform().position
-- vector(5.0000, -2.5000, -10.0000)
```

The following statements first store the world transform of the model named Tire in the variable `tempTransform`, then they display the position component of that transform.
```
tempTransform = member("scene").model("Tire").getWorldTransform()
put tempTransform.position
-- vector(5.0000, -2.5000, -10.0000)
```

See also

- `transform (property)`, `getWorldTransform()`, `rotation (transform)`, `scale (transform)`

positionReset

Usage

```
member(whichCastmember).model(whichModel).bonesPlayer.
  positionReset
member(whichCastmember).model(whichModel).keyframePlayer.
  positionReset
```

Description

3D `keyframePlayer` and `bonesPlayer` modifier property; indicates whether the model returns to its starting position after the end of a motion (`TRUE`) or not (`FALSE`).

The default value for this property is `TRUE`.

Example

This statement prevents the model Monster from returning to its original position when it finishes the execution of a motion:
```
member("NewAlien").model("Monster").keyframePlayer.
  positionReset = FALSE
```

See also

- `currentLoopState`
posterFrame

Usage

-- Lingo syntax
memberObjRef.posterFrame

// JavaScript syntax
memberObjRef.posterFrame;

Description

Flash cast member property; controls which frame of a Flash movie cast member is used for its
thumbnail image. This property specifies an integer corresponding to a frame number in the
Flash movie.

This property can be tested and set. The default value is 1.

Example

This handler accepts a reference to a Flash movie cast member and a frame number as parameters,
and it then sets the thumbnail of the specified movie to the specified frame number:

-- Lingo syntax
on resetThumbnail(whichFlashMovie, whichFrame)
    member(whichFlashMovie).posterFrame = whichFrame
end

// JavaScript syntax
function resetThumbnail(whichFlashMovie, whichFrame) {
    member(whichFlashMovie).posterFrame = whichFrame;
}

preferred3dRenderer

Usage

-- Lingo syntax
_movie.preferred3dRenderer

// JavaScript syntax
_movie.preferred3dRenderer;

Description

Movie property; allows you to get or set the default renderer used to draw 3D sprites within a
particular movie if that renderer is available on the client machine. Read/write.

If the specified renderer is not available on the client machine, the movie selects the most suitable
available renderer.

The possible values for this property are as follows:

- #openGL specifies the OpenGL drivers for a hardware acceleration that work with both
  Macintosh and Windows platforms.
- #directX7_0 specifies the DirectX 7 drivers for hardware acceleration that work only with
  Windows platforms.
- #directX5_2 specifies the DirectX 5.2 drivers for hardware acceleration that work only with
  Windows platforms.
• #software specifies the Director built-in software renderer that works with both Macintosh and Windows platforms.
• #auto specifies that the most suitable renderer should be chosen. This is the default value for this property.

The value set for this property is used as the default for the Renderer Services object’s renderer property.

This property differs from the getRendererServices() object’s renderer property in that the preferred3dRenderer specifies the preferred renderer to use, whereas the getRendererServices() object’s renderer property indicates what renderer is actually being used by the movie.

Shockwave Player users have the option of specifying the renderer of their choice using the 3D Renderer context menu in Shockwave Player. If the user selects the “Obey content settings” option, the renderer specified by the renderer or preferred3DRenderer property is used to draw the movie (if available on the user’s system), otherwise, the renderer selected by the user is used.

Example
This statement allows the movie to pick the best 3D renderer available on the user’s system:

-- Lingo syntax
_movie.preferred3dRenderer = #auto

// JavaScript syntax
_movie.preferred3dRenderer = "auto";

See also
getRendererServices(), Movie, renderer

preLoad (3D)

Usage
member(whichCastmember).preload
memberReference.preload

Description
3D property; allows you to get or set whether data is preloaded before playing (TRUE), or is streamed while playing (FALSE). This property can be used only with linked files. The default value is FALSE.

In Director, setting the preLoad property to TRUE causes the cast member to load completely before playback starts. In Shockwave Player, setting the preLoad property to TRUE causes the cast member to begin streaming when the movie starts playing. Before performing any Lingo operations on a 3D cast member that is streaming, be sure to check that the cast member’s state property has a value greater than or equal to 2.

Example
This statement sets the preload property of the cast member PartyScene to FALSE, which allows externally linked media to stream into PartyScene during playback:

ember("PartyScene").preload = FALSE
member("3D world").preload
See also
  state (3D)

preLoad (Member)

Usage
  -- Lingo syntax
  memberObjRef.preLoad

  // JavaScript syntax
  memberObjRef.preLoad;

Description
  Cast member property; determines whether the digital video cast member specified by
  whichCastMember can be preloaded into memory (TRUE) or not (FALSE, default). The TRUE
  status has the same effect as selecting Enable Preload in the Digital Video Cast Member
  Properties dialog box.

  For Flash movie cast members, this property controls whether a Flash movie must load entirely
  into RAM before the first frame of a sprite is displayed (TRUE), or whether the movie can stream
  into memory as it plays (FALSE, default). This property works only for linked Flash movies whose
  assets are stored in an external file; it has no effect on members whose assets are stored in the cast.
  The streamMode and bufferSize properties determine how the cast member is streamed into
  memory.

  This property can be tested and set.

Example
  This statement reports in the Message window whether the QuickTime movie Rotating Chair can
  be preloaded into memory:

  -- Lingo syntax
  put(member("Rotating Chair").preload)

  // JavaScript syntax
  put(member("Rotating Chair").preload);

See also
  bufferSize, streamMode

preLoadEventAbort

Usage
  -- Lingo syntax
  _movie.preLoadEventAbort

  // JavaScript syntax
  _movie.preLoadEventAbort;

Description
  Movie property; specifies whether pressing keys or clicking the mouse can stop the preloading of
  cast members (TRUE) or not (FALSE, default). Read/write.

  Setting this property affects the current movie.
Example
This statement lets the user stop the preloading of cast members by pressing keys or clicking the mouse button:

-- Lingo syntax
_movie.preLoadEventAbort = TRUE

// JavaScript syntax
_movie.preLoadEventAbort = true;

See also
Movie

preLoadMode

Usage

-- Lingo syntax
castObjRef.preLoadMode

// JavaScript syntax
castObjRef.preLoadMode;

Description
Cast library property; determines the preload mode of a specified cast library. Read/write.

Valid values of preLoadMode are:
• 0. Load the cast library when needed. This is the default value.
• 1. Load the cast library before frame 1.
• 2. Load the cast library after frame 1.

Setting this property has the same effect as setting Load Cast in the Cast Properties dialog box.

Example
The following statement tells Director to load the members of the cast named Buttons before the movie enters frame 1:

-- Lingo syntax
castLib("Buttons").preLoadMode = 1

// JavaScript syntax
castLib("Buttons").preLoadMode = 1;

See also
Cast Library
**preLoadRAM**

**Usage**

the preLoadRAM

**Description**

System property; specifies the amount of RAM that can be used for preloading a digital video. This property can be set and tested.

This property is useful for managing memory, limiting digital video cast members to a certain amount of memory, so that other types of cast members can still be preloaded. When `preLoadRAM` is `FALSE`, all available memory can be used for preloading digital video cast members.

However, it's not possible to reliably predict how much RAM a digital video will require once it is preloaded, because memory requirements are affected by the content of the movie, how much compression was performed, the number of keyframes, changing imagery, and so on.

It is usually safe to preload the first couple of seconds of a video and then continue streaming from that point on.

If you know the data rate of your movie, you can estimate the setting for `preLoadRAM`. For example, if your movie has a data rate of 300K per second, set `preLoadRAM` to 600K if you want to preload the first 2 seconds of the video file. This is only an estimate, but it works in most situations.

**Example**

This statement sets `preLoadRAM` to 600K, to preload the first 2 seconds of a movie with a data rate of 300K per second:

```
set the preLoadRAM = 600
```

**See also**

`loop` (keyword), `next`

---

**preLoadTime**

**Usage**

```-- Lingo syntax
memberObjRef.preLoadTime
```  

```// JavaScript syntax
memberObjRef.preLoadTime;
```  

**Description**

Cast member and sound channel property; for cast members, specifies the amount of the Shockwave Audio (SWA) streaming cast member to download, in seconds, before playback begins or when a `preLoadBuffer` command is used. The default value is 5 seconds.

This property can be set only when the SWA streaming cast member is stopped.

For sound channels, the value is for the given sound in the queue or the currently playing sound if none is specified.
Example

The following handler sets the preload download time for the SWA streaming cast member Louis Armstrong to 6 seconds. The actual preload occurs when a `preLoadBuffer` or `play` command is issued.

```
-- Lingo syntax
on mouseDown
  member("Louis Armstrong").stop()
  member("Louis Armstrong").preloadTime = 6
end

// JavaScript syntax
function mouseDown() {
  member("Louis Armstrong").stop();
  member("Louis Armstrong").preloadTime = 6;
}
```

This statement returns the `preloadTime` of the currently playing sound in sound channel 1:

```
-- Lingo syntax
put sound(1).preloadTime

// JavaScript syntax
trace(sound(1).preloadTime);
```

See also

`preLoadBuffer()`

**primitives**

**Usage**

```
getRendererServices().primitives
```

**Description**

3D function; returns a list of the primitive types that can be used to create new model resources.

**Example**

This statement display the available primitive types:

```
put getRendererServices().primitives
-- [sphere, box, cylinder, plane, particle]
```

See also

`getRendererServices().newModelResource`

**productName**

**Usage**

```
-- Lingo syntax
_player.productName

// JavaScript syntax
_player.productName;
```

**Description**

Player property; returns the name of the Director application. Read-only.
Example
This statement displays in the Message window the name of the Director application.

-- Lingo syntax
trace(_player.productName)

// JavaScript syntax
trace(_player.productName);

See also
Player

productVersion

Usage
-- Lingo syntax
_player.productVersion

// JavaScript syntax
_player.productVersion;

Description
Player property; returns the version number of the Director application. Read-only.

Example
This statement displays in the Message window the version of the Director application.

-- Lingo syntax
trace(_player.productVersion)

// JavaScript syntax
trace(_player.productVersion);

See also
Player

projection

Usage
sprite(whichSprite).camera.projection
camera(whichCamera).projection
member(whichCastmember).camera(whichCamera).projection

Description
3D property; allows you to get or set the projection style of the camera. Possible values are #perspective (the default) and #orthographic.

When projection is #perspective, objects closer to the camera appear larger than objects farther from the camera, and the projectionAngle or fieldOfView properties specify the vertical projection angle (which determines how much of the world you see). The horizontal projection angle is determined by the aspect ratio of the camera's rect property.
When projection is \texttt{#orthographic}, the apparent size of objects does not depend on distance from the camera, and the \texttt{orthoHeight} property specifies how many world units fit vertically into the sprite (which determines how much of the world you see). The orthographic projection width is determined by the aspect ratio of the camera's \texttt{rect} property.

\textbf{Example}

This statement sets the projection property of the camera of sprite 5 to \texttt{#orthographic}:
\[
sprite(5).camera.projection = \texttt{#orthographic}
\]

\textbf{See also}

\texttt{fieldOfView (3D), orthoHeight, fieldOfView (3D)}

\textit{purgePriority}

\textbf{Usage}

\begin{itemize}
  \item \texttt{-- Lingo syntax}
    \[
    \text{memberObjRef}.purgePriority
    \]
  \item \texttt{-- JavaScript syntax}
    \[
    \text{memberObjRef}.purgePriority;
    \]
\end{itemize}

\textbf{Description}

Member property; specifies the purge priority of a cast member. Read/write.

A cast member's purge priorities determine the priority that Director follows to choose which cast members to delete from memory when memory is full. The higher the purge priority, the more likely that the cast member will be deleted. The following \texttt{purgePriority} settings are available:

\begin{itemize}
  \item 0—Never
  \item 1—Last
  \item 2—Next
  \item 3—Normal (default)
\end{itemize}

The Normal setting lets Director purge cast members from memory at random. The Next, Last, and Never settings allow some control over purging, but Last or Never may cause your movie to run out of memory if several cast members are set to these values.

Setting \texttt{purgePriority} for cast members is useful for managing memory when the size of the movie's cast library exceeds the available memory. As a general rule, you can minimize pauses while the movie loads cast members and reduce the number of times Director reloads a cast member by assigning a low purge priority to cast members that are used frequently in the course of the movie.

\textbf{Example}

This statement sets the purge priority of cast member \texttt{Background} to 3, which makes it one of the first cast members to be purged when memory is needed:

\begin{itemize}
  \item \texttt{-- Lingo syntax}
    \[
    \text{member("Background").purgePriority = 3}
    \]
  \item \texttt{-- JavaScript syntax}
    \[
    \text{member("Background").purgePriority = 3;}
    \]
\end{itemize}
quad

Usage

-- Lingo syntax
spriteObjRef.quad

// JavaScript syntax
spriteObjRef.quad;

Description

Sprite property; contains a list of four points, which are floating point values that describe the
corner points of a sprite on the Stage. Read/write.

The points of the quad are organized in the following order: upper left, upper right, lower right,
and lower left.

The points themselves can be manipulated to create perspective and other image distortions.

After you manipulate the quad of a sprite, you can reset it to the Score values by turning off the
scripted sprite with puppetSprite(intSpriteNum, FALSE). When the quad of a sprite is
disabled, you cannot rotate or skew the sprite.

Example

This statement displays a typical list describing a sprite:

-- Lingo syntax
put(sprite(1).quad)

// JavaScript syntax
put(sprite(1).quad);

When modifying the quad sprite property, you must reset the list of points after changing any of
the values. This is because when you set a variable to the value of a property, you are placing a
copy of the list, not the list itself, in the variable. To effect a change, use syntax like this (applies to
Lingo only):

-- Lingo syntax
currQuadList = sprite(5).quad
currQuadList[1] = currQuadList[1] + point(50, 50)
sprite(5).quad = currQuadList

See also

point(), puppetSprite(), Sprite
quality

Usage

-- Lingo syntax
memberOrSpriteObjRef.quality

// JavaScript syntax
memberOrSpriteObjRef.quality;

Description

Flash cast member and sprite property; controls whether Director uses anti-aliasing to render a Flash movie sprite, producing high-quality rendering but possibly slower movie playback. The quality property can have these values:

- #autoHigh—Director starts by rendering the sprite with anti-aliasing. If the actual frame rate falls below the movie's specified frame rate, Director turns off anti-aliasing. This setting gives precedence to playback speed over visual quality.
- #autoLow—Director starts by rendering the movie without anti-aliasing. If the Flash player determines that the computer processor can handle it, anti-aliasing is turned on. This setting gives precedence to visual quality whenever possible.
- #high (default)—The movie always plays with anti-aliasing.
- #low—The movie always plays without anti-aliasing.

The quality property can be tested and set.

Example

The following sprite script checks the color depth of the computer on which the movie is playing. If the color depth is set to 8 bits or less (256 colors), the script sets the quality of the sprite in channel 5 to #low.

-- Lingo syntax
on beginSprite me
  if _system.colorDepth <= 8 then
    sprite(1).quality = #low
  end if
end

// JavaScript syntax
function beginSprite() {
  var clrDp = _system.colorDepth;
  if (clrDp <= 8) {
    sprite(1).quality = symbol("low");
  }
}
quality (3D)

Usage
member(whichCastmember).texture(whichTexture).quality
member(whichCastmember).shader(whichShader).texture(whichTexture).quality
member(whichCastmember).model(whichModel).shader.texture(whichTexture).quality
member(whichCastmember).model(whichModel).shaderList.shaderList[r].texture(whichTexture).quality
member(whichCastmember).model(whichModel).shaderList[shaderListIndex].texturelist[TextureListIndex].quality

Description
3D texture property; lets you get or set the image quality of a texture by controlling the level of mipmapping applied to the texture. Mipmapping is a process by which additional versions of the texture image are created in several sizes that are smaller than the original image. The 3D Xtra extension then uses whichever version of the image is most appropriate to the current size of the model on the screen and changes the version of the image that is being used when needed.

Trilinear mipmapping is higher in quality and uses more memory than bilinear mipmapping. Mipmapping is not the same as filtering, although both improve texture appearance. Filtering spreads errors out across the texture's area so that errors are less concentrated. Mipmapping resamples the image to make it the appropriate size.

This property can have the following values:

• #low is the same as off, and mipmapping is not used for the texture.
• #medium enables a low-quality (bilinear) mipmapping for the texture.
• #high enables a high-quality (trilinear) mipmapping for the texture.

The default is #low.

Example
This statement sets the quality property of the texture Marsmap to #medium:
member("scene").texture("Marsmap").quality = #medium

See also
nearFiltering

radius

Usage
modelResourceObjectReference.radius
member(whichCastmember).modelResource(whichModelResource).radius

Description
3D model property; when used with model resource of type #sphere or #cylinder, allows you to get or set the radius of the model.

The radius property determines the sweep radius used to generate the model resource. This property's value must always be set to greater than 0.0, and has a default value of 25.0.
Example

This example shows that the radius of the model resource Sphere01 is 24.0:

```
put member("3D World").modelResource("Sphere01").radius
-- 24.0
```

randomSeed

Usage

the randomSeed

Description

System property; specifies the seed value used for generating random numbers accessed through the random() function.

Using the same seed produces the same sequence of random numbers. This property can be useful for debugging during development. Using the ticks property is an easy way to produce a unique random seed since the ticks value is highly unlikely to be duplicated on subsequent uses.

This property can be tested and set.

Example

This statement displays the random seed number in the Message window:

```
put the randomSeed
```

See also

random(), milliseconds

recordFont

Usage

```
recordFont(whichCastMember, font {[,.face]} {[,.bitmapSizes]} [.characterSubset] [{,.userFontName}])
```

Description

Command; embeds a TrueType or Type 1 font as a cast member. Once embedded, these fonts are available to the author just like other fonts installed in the system.

You must create an empty font cast member with the new() command before using recordFont.

- **font**—Name of original font to be recorded.
- **face**—List of symbols indicating the face of the original font; possible values are plain, bold, italic. If you do not provide a value for this argument, plain is used.
- **bitmapSizes**—List of integers specifying the sizes for which bitmaps are to be recorded. This argument can be empty. If you omit this argument, no bitmaps are generated. These bitmaps typically look better at smaller point sizes (below 14 points) but take up more memory.
- **characterSubset**—String of characters to be encoded. Only the specified characters will be available in the font. If this argument is, all characters are encoded. If only certain characters are encoded but an unencoded character is used, that character is displayed as an empty box.
- **userFontName**—A string to use as the name of the newly recorded font cast member.
The command creates a Shock Font in *whichCastMember* using the font named in the *font* argument. The value returned from the command reports whether the operation was successful. Zero indicates success.

**Example**

This statement creates a simple Shock Font using only the two arguments for the cast member and the font to record:

```plaintext
myNewFontMember = new(#font)
recordFont(myNewFontMember, "Lunar Lander")
```

This statement specifies the bitmap sizes to be generated and the characters for which the font data should be created:

```plaintext
myNewFontMember = new(#font)
recordfont(mynewmember,"lunar lander", [], [14, 18, 45], "Lunar Lander Game High \ Score First Last Name")
```

**Note:** Since *recordFont* resynthesizes the font data rather than using it directly, there are no legal restrictions on Shock Font distribution.

**See also**

new()

---

**rect (camera)**

**Usage**

```plaintext
sprite(whichSprite).camera(whichCamera).rect
```

**Description**

3D camera property; allows you to get or set the rectangle that controls the size and position of the camera. This rectangle is analogous to the rectangle you see through the eyepiece of a real camera.

The default value for the rect property for all cameras rect(0,0,1,1) which makes them invisible until you change the setting. However, when `sprite.camera(1)` is rendered, its rect is reset to `rect(0.0, sprite(whichSprite).width, sprite(whichSprite).height)` so that the camera fills the screen. All camera rect coordinates are given relative to the top left corner of the sprite.

If *whichCamera* is greater than 1, the rect is not scaled when the sprite is scaled, so it will be necessary to manage that with script if desired.

When *whichCamera* is greater than 1, the rect.top and rect.left properties must be greater than or equal to the rect.top and rect.left settings for `sprite.camera(1)`.

**Example**

This statement sets the rect of the default camera of sprite 5 to rect(0, 0, 200, 550):

```plaintext
sprite(5).camera.rect = rect(0.0, 200, 550)
```

**See also**

`cameraPosition, cameraRotation`
rect (Image)

Usage

-- Lingo syntax
imageObjRef.rect

// JavaScript syntax
imageObjRef.rect;

Description

Image property. Returns a rectangle describing the size of a given image. Read-only.

The returned rectangle coordinates are given relative to the top left corner of the image.
Therefore, the left and top values of the rectangle are 0, and the right and bottom values are the
width and height of the cast member.

Example

This statement returns the rectangle of the 300 x 400 pixel member Sunrise in the
message window:

-- Lingo syntax
member("Sunrise").image.rect -- rect(0, 0, 300, 400)

// JavaScript syntax
member("Sunrise").image.rect; // rect(0, 0, 300, 400)

This Lingo looks at the first 50 cast members and displays the rectangle and name of each cast
member that is a bitmap:

-- Lingo syntax
on showAllRects
  repeat with x = 1 to 50
    if member(x).type = #bitmap then
      put member(x).image.rect && " - " && member(x).name
    end if
  end repeat
end

// JavaScript syntax
function showAllRects() {
  var x = 1;
  while(x < 51) {
    var tp = member(x).type;
    if (tp = "bitmap") {
      trace(member(x).image.rect + " - " + member(x).name);
      i++;
    }
  }
}

See also

height, image(), width
rect (Member)

Usage

-- Lingo syntax
memberObjRef.rect

// JavaScript syntax
memberObjRef.rect;

Description

Member property; specifies the left, top, right, and bottom coordinates, returned as a rectangle, for the rectangle of any graphic cast member, such as a bitmap, shape, movie, or digital video. Read-only for all cast members, read/write for field cast members only.

For a bitmap, the rect property is measured from the upper left corner of the bitmap, instead of from the upper left corner of the easel in the Paint window.

For an Xtra extension cast member, the rect property is a rectangle whose upper left corner is at (0,0).

Example

This statement displays the coordinates of bitmap cast member 20:

-- Lingo syntax
put(member(20).rect)

// JavaScript syntax
put(member(20).rect);

This statement sets the coordinates of bitmap cast member Banner:

-- Lingo syntax
member("Banner").rect = rect(100, 150, 300, 400)

// JavaScript syntax
member("Banner").rect = rect(100, 150, 300, 400);

See also

Member

rect (Sprite)

Usage

-- Lingo syntax
spriteObjRef.rect

// JavaScript syntax
spriteObjRef.rect;

Description

Sprite property; specifies the left, top, right, and bottom coordinates, as a rectangle, for the rectangle of any graphic sprite such as a bitmap, shape, movie, or digital video. Read/write.
Example

This statement displays the coordinates of bitmap sprite 20:

```-- Lingo syntax
put(sprite(20).rect)
// JavaScript syntax
put(sprite(20).rect);
```

See also

rect(), Sprite

rect (Window)

Usage

```-- Lingo syntax
windowObjRef.rect
// JavaScript syntax
windowObjRef.rect;
```

Description

Window property; specifies the left, top, right, and bottom coordinates, as a rectangle, of a window. Read/write.

If the size of the rectangle specified is less than that of the Stage where the movie was created, the movie is cropped in the window, not resized.

To pan or scale the movie playing in the window, set the drawRect or sourceRect property of the window.

Example

This statement displays the coordinates of the window named Control_panel:

```-- Lingo syntax
put(window("Control_panel").rect)
// JavaScript syntax
put(window("Control_panel").rect);
```

See also

drawRect, sourceRect, Window

ref

Usage

`chunkExpression.ref`

Description

Text chunk expression property; this provides a convenient way to refer to a chunk expression within a text cast member.
**Example**

Without references, you would need statements like these:

```plaintext
member(whichTextMember).line[whichLine].word[firstWord..lastWord].font = "Palatino"
member(whichTextMember).line[whichLine].word[firstWord..lastWord].fontSize = 36
member(whichTextMember).line[whichLine].word[firstWord..lastWord].fontStyle = [#bold]
```

But with a `ref` property, you can refer to the same chunk as follows:

```plaintext
myRef = member(whichTextMember).line[whichLine].word[firstWord..lastWord].ref
```

The variable `myRef` is now shorthand for the entire chunk expression. This allows something like the following:

```plaintext
put myRef.font
-- "Palatino"
```

Or you can set a property of the chunk as follows:

```plaintext
myRef.fontSize = 18
myRef.fontStyle = [#italic]
```

You can get access to the string referred to by the reference using the `text` property of the reference:

```plaintext
put myRef.text
```

This would result in the actual string data, not information about the string.

**reflectionMap**

**Usage**

```plaintext
member(whichCastmember).shader(whichShader).reflectionMap
```

**Description**

3D shader property; allows you to get and set the texture used to create reflections on the surface of a model. This texture is applied to the third texture layer of the shader. This property is ignored if the `toon` modifier is applied to the model resource.

This helper property provides a simple interface for setting up a common use of reflection mapping. The same effect can be achieved by setting the following properties:

```plaintext
shader.textureModeList[3] = #reflection
shader.blendFunctionList[3] = #blend
shader.blendSourceList[3] = #constant
shader.blendConstantList[3] = 50.0
```

When tested, this property returns the texture associated with the model’s third texture layer. The default is `void`.

**Example**

This statement causes the model named GlassSphere to appear to reflect the texture named Portrait off of its surface:

```plaintext
member("3DPlanet").model("GlassSphere").shader.reflectionMap = \nmember("3DPlanet").texture("Portrait")
```
See also

textureModeList, blendFunctionList, blendConstantList

**reflectivity**

Usage

member(whichCastmember).reflectivity

Description

3D shader property; allows you to get or set the shininess of the referenced member's default shader. The value is a floating point value representing the percentage of light to be reflected off the surface of a model using the default shader, from 0.0 to 100.00. The default value is 0.0.

Example

This statement sets the shininess of the default shader in the cast member named Scene to 50%:

member("Scene").reflectivity = 50

**region**

Usage

member(whichCastmember).modelResource(whichModelResource).emitter.region

Description

3D emitter property; when used with a model resource whose type is #particle, allows you to both get and set the region property of the resource's particle emitter.

The region property defines the location from which particles are emitted. If its value is a single vector, then that vector is used to define a point in the 3D world from which particles will be emitted.

If its value is a list of two vectors, then those vectors are used to define the end points of a line segment from which particles will be emitted.

If its value is a list of four vectors, then those vectors are used to define the vertices of a quadrilateral from which the particles will be emitted.

The default value for this property is [vector(0,0,0)].

Example

In this example, ThermoSystem is a model resource of the type #particle. This statement specifies the four corners of a rectangle from which the particles of ThermoSystem originate.

member("Fires").modelResource("ThermoSystem").emitter.region = [vector(20,90,100), vector(30,90,100), vector(30,100,100), vector(20,100,100)]

See also

descriptor
**regPoint**

**Usage**

-- Lingo syntax
memberObjRef.regPoint

// JavaScript syntax
memberObjRef.regPoint;

**Description**

Member property; specifies the registration point of a cast member. Read/write.

The registration point is listed as the horizontal and vertical coordinates of a point in the form `point(horizontal, vertical)`. Nonvisual members such as sounds do not have a useful `regPoint` property.

You can use the `regPoint` property to animate individual graphics in a film loop, changing the film loop's position in relation to other objects on the Stage.

You can also use `regPoint` to adjust the position of a mask being used on a sprite.

When a Flash movie cast member is first inserted into the cast library, its registration point is its center and its `centerRegPoint` property is set to `TRUE`. If you subsequently use the `regPoint` property to reposition the registration point, the `centerRegPoint` property is automatically set to `FALSE`.

**Example**

This statement displays the registration point of the bitmap cast member Desk in the Message window:

-- Lingo syntax
put(member("Desk").regPoint)

// JavaScript syntax
put(member("Desk").regPoint);

This statement changes the registration point of the bitmap cast member Desk to the values in the list:

-- Lingo syntax
member("Desk").regPoint = point(300, 400)

// JavaScript syntax
member("Desk").regPoint = point(300, 400);

**See also**

Member, Sprite
regPoint (3D)

Usage

```lingo
sprite(whichSprite).camera.backdrop[backdropIndex].regPoint
member(whichCastmember).camera(whichCamera).backdrop[backdropIndex].regPoint
```

Description

3D backdrop and overlay property; allows you to get or set the registration point of the backdrop or overlay. The registration point represents the x, y, and z coordinates of the center of the backdrop or overlay in 3D space. The default value for this property is point(0,0).

Example

The following statement changes the registration point of the first backdrop of the camera of sprite 13. The backdrop's registration point will be the point (50, 0), measured from the upper left corner of the backdrop.

```lingo
sprite(13).camera.backdrop[1].regPoint = point(50, 0)
```

See also

loc (backdrop and overlay)

regPointVertex

Usage

```lingo
-- Lingo syntax
memberObjRef.regPointVertex

// JavaScript syntax
memberObjRef.regPointVertex;
```

Description

Cast member property; indicates whether a vertex of `vectorCastMember` is used as the registration point for that cast member. If the value is zero, the registration point is determined normally, using the `centerRegPoint` and `regPoint` properties. If the value is nonzero, it indicates the position in the `vertextList` of the vertex being used as the registration point. The `centerRegPoint` is set to `FALSE` and the `regPoint` is set to the location of that vertex.

Example

This statement makes the registration point for the vector shape cast member `Squiggle` correspond to the location of the third vertex:

```lingo
-- Lingo syntax
member("squiggle").regPointVertex=3

// JavaScript syntax
member("squiggle").regPointVertex=3;
```

See also

`centerRegPoint`, `regPoint`
renderer

Usage
getRendererServices().renderer

Description
3D property; allows you to get or set the current renderer in use by a movie. The range of values for this property is determined by the list of available renderers returned by the Renderer Services object's rendererDeviceList property.

Shockwave Player users have the option of specifying the renderer of their choice using the 3D Renderer context menu in Shockwave Player. If the user selects the “Obey content settings” option, the renderer specified by the renderer or preferred3DRenderer properties is used to draw the movie (if available on the users system), otherwise the renderer selected by the user is used.

The default value for this property is determined by the preferred3DRenderer property.

This property returns the same value as returned by the movie property the active3dRenderer.

Example
This statement shows that the renderer currently being used by the user's system is #openGL:
put getRendererServices().renderer
-- #openGL

See also
getRendererServices(), preferred3DRenderer, rendererDeviceList, active3dRenderer

rendererDeviceList

Usage
getRendererServices().rendererDeviceList

Description
3D renderer property; returns a list of symbols identifying the renderers that are available for use on the client machine. The contents of this list determine the range of values that can be specified for the renderer and preferred3DRenderer properties. This property can be tested but not set.

This property is a list that can contain the following possible values:

• #openGL specifies the openGL drivers for a hardware acceleration which work with both Macintosh and Windows platforms.
• #directX7_0 specifies the DirectX 7 drivers for hardware acceleration which work with Windows platforms only.
• #directX5_2 specifies the DirectX 5.2 drivers for hardware acceleration which work with Windows platforms only.
• #software specifies the Director built-in software renderer which works with both Macintosh and Windows platforms.
Example

This statement shows the renderers available on the current system:

```perl
put getRendererServices().rendererDeviceList
-- [#OpenGL, #software]
```

See also

`getRendererServices()`, `renderer`, `preferred3dRenderer`, `active3dRenderer`

renderFormat

Usage

```perl
member(whichCastmember).texture(whichTexture).renderFormat
member(whichCastmember).texture[index].renderFormat
member(whichCastmember).shader(whichShader).texture.renderFormat
member(whichCastmember).model(whichModel).shader.texture\renderFormat
member(whichCastmember).model(whichModel).shader.textureList\[index].renderFormat
member(whichCastmember).model(whichModel).shaderList[index].\texture(whichTexture).renderFormat
member(whichCastmember).model(whichModel).shaderList[index].\textureList[index].renderFormat
```

Description

3D property; allows you to get or set the `textureRenderFormat` for a specific texture by specifying one of the following values:

- `#default` uses the value returned by `getRendererServices().textureRenderFormat`.
- `rgba8888`
- `rgba8880`
- `rgba5650`
- `rgba5550`
- `rgba5551`
- `rgba4444`

See `textureRenderFormat` for information on these values.

Setting this property for an individual texture overrides the global setting set using `textureRenderFormat`.

The `renderFormat` property determines the pixel format the renderer uses when rendering the specified texture. Each pixel format has a number of digits, with each digit indicating the color depth being used for red, green, blue, and alpha. The value you choose determines the accuracy of the color fidelity (including the precision of the optional alpha channel) and thus the amount of memory used on the video card. You can choose a value that improves color fidelity or a value that allows you to fit more textures into memory on the video card. You can fit roughly twice as many 16-bit textures as 32-bit textures in the same space.

Example

The following statement sets the `renderFormat` property of the texture `TexPic` to `rgba4444`. The red, blue, green, and alpha components of the texture will each be drawn using 4 bits of information.

```perl
member("3d").texture("TexPic").renderFormat = #rgba4444
```
renderStyle

Usage
member(whichCastmember).shader(whichShader).renderStyle

Description
3D standard shader property; allows you to get or set the renderStyle for a shader, as determined by the geometry of the underlying model resource. This property has the following values:

#fill specifies that the shader is drawn to completely fill the surface area of the model resource.
#wire specifies that the shader is drawn only on the edges of the faces of the model resource.
#point specifies that the shader is drawn only on the vertices of the model resource.

All shaders have access to the #standard shader properties; in addition to these standard shader properties shaders of the types #engraver, #newsprint, and #painter have properties unique to their type. For more information, see newShader.

Example
This statement causes the shader WallMaterial to be rendered only where it lies on top of a vertex of the underlying model resource:
member("CityScene").shader("WallMaterial").renderStyle = #point

resizable

Usage
-- Lingo syntax
windowObjRef.resizable

// JavaScript syntax
windowObjRef.resizable;

Description
Window property; specifies whether the window is resizable (TRUE, default) or not (FALSE). Read/write.

Example
These statements maximize the window named Empire if the window is resizable.

-- Lingo syntax
if (window("Empire").resizable = TRUE) then
  window("Empire").maximize()
end if

// JavaScript syntax
if (window("Empire").resizable = true) {
  window("Empire").maximize();
}
See also

Window

resolution (3D)

Usage

member(\texttt{whichCastmember}).modelResource(\texttt{whichModelResource}).resolution

Description

3D property; allows you to get or set the resolution property of a model resource whose type is either \texttt{#sphere} or \texttt{#cylinder}.

Resolution controls the number of polygons used to generate the geometry of the model resource. A larger value generates more polygons and thus results in a smoother surface. The default value of this property is 20.

Example

This statement sets the resolution of the model resource named \texttt{sphere01} to 10.0:

\begin{verbatim}
member("3D World").modelResource("sphere01").resolution = 10.0
\end{verbatim}

resolution (DVD)

Usage

\begin{verbatim}
-- Lingo syntax
dvdObjRef.resolution

// JavaScript syntax
dvdObjRef.resolution;
\end{verbatim}

Description

DVD property. Returns a property list that contains the $x$-axis (width) and $y$-axis (height) source resolution. Read-only.

Possible $x$-axis values are 352, 704, or 720.
Possible $y$-axis values are 240, 480, 288, or 576.

Example

This statement returns a sample property list of resolutions:

\begin{verbatim}
-- Lingo syntax
trace(member(1).resolution) -- [\texttt{#width}: 720, \texttt{#height}: 480]

// JavaScript syntax
trace(member(1).resolution); // ["width": 720, "height": 480]
\end{verbatim}

See also

DVD
**resolve**

**Usage**

```
member(whichCastmember).model(whichModel).collision.resolve
```

**Description**

3D collision property; allows you to get or set whether collisions are resolved when two models collide. If this property is set to `TRUE` for both models involved in a collision, both models come to a stop at the point of collision. If only one of the models has the `resolve` property set to `TRUE`, that model comes to a stop, and the model with the property not set, or set to `FALSE`, continues to move. The default value for this property is `TRUE`.

**Example**

The following statement sets the `resolve` property of the collision modifier applied to the model named `Box` to `TRUE`. When the model named `Box` collides with another model that has the `#collision` modifier attached, it will stop moving.

```
member("3d world").model("Box").collision.resolve = TRUE
```

**See also**

`collisionData`, `collisionNormal`, `modelA`, `modelB`, `pointOfContact`

**resource**

**Usage**

```
member(whichCastmember).model(whichModel).resource
```

**Description**

3D property; allows you to get or set the resource property that defines the geometry of the referenced model resource. This property also allows access to the referenced model’s resource object and its associated properties.

**Example**

The following statement sets the model resource used by the model named `NewBox`. It will now have the same geometry as the model named `box`.

```
member("3d World").model("NewBox").resource = member("3d World").model("box").resource
```

This statement displays the resolution property of the model resource used by the model named `Cylinder`.

```
put member("3d World").model("Cylinder").resource.resolution
-- 20
```
right

Usage
-- Lingo syntax
spriteObjRef.right

// JavaScript syntax
spriteObjRef.right;

Description
Sprite property; indicates the distance, in pixels, of a sprite's right edge from the left edge of the Stage. Read/write.

Sprite coordinates are expressed relative to the upper left corner of the Stage.

Example
This statement returns the distance of a sprite's right edge:
-- Lingo syntax
put(sprite(6).right)

// JavaScript syntax
put(sprite(6).right);

See also
bottom, height, left, locH, locV, Sprite, top, width

right (3D)

Usage
member(whichCastmember).modelResource
(whichModelResource).right
modelResourceObjectReference.right

Description
3D property; allows you to get or set the right property of a model resource whose type is #box.

The right property determines whether the right of the box is sealed (TRUE) or open (FALSE).
The default value is TRUE.

Example
This statement sets the right property of the model resource Crate to TRUE, meaning the right side of this box will be closed:
member("3D World").modelResource("crate").right = TRUE

See also
bottom (3D), left (3D), top (3D)
rightIndent

Usage
chunkExpression.rightIndent

Description
Text cast member property; contains the offset distance, in pixels, of the right margin of chunkExpression from the right side of the text cast member.
The value is an integer greater than or equal to 0.
This property can be tested and set.
See also
firstIndent, leftIndent

rightMouseDown

Usage
-- Lingo syntax
_mouse.rightMouseDown

// JavaScript syntax
_mouse.rightMouseDown;

Description
Mouse property; indicates whether the right mouse button (Windows) or the mouse button and Control key (Macintosh) are being pressed (TRUE) or not (FALSE). Read-only.
On the Macintosh, rightMouseDown is TRUE only if the emulateMultibuttonMouse property is TRUE.

Example
This statement checks whether the right mouse button in Windows is being pressed and plays the sound Oops in sound channel 2 if it is:

-- Lingo syntax
if (_mouse.rightMouseDown) then
    sound(2).play(member("Oops"))
end if

// JavaScript syntax
if (_mouse.rightMouseDown) {
    sound(2).play(member("Oops"));
}

See also
emulateMultibuttonMouse, Mouse
rightMouseUp

Usage
-- Lingo syntax
_mouse.rightMouseUp

// JavaScript syntax
_mouse.rightMouseUp;

Description
Mouse property; indicates whether the right mouse button (Windows) or the mouse button and
Control key (Macintosh) are currently not being pressed (TRUE) or are currently being pressed
(FALSE). Read-only.

On the Macintosh, rightMouseUp is TRUE only if the emulateMultiButtonMouse property
is TRUE.

Example
This statement checks whether the right mouse button in Windows is released and plays the
sound Click Me if it is:

-- Lingo syntax
if (_mouse.rightMouseUp) then
    sound(2).play(member("Click Me"));
end if

// JavaScript syntax
if (_mouse.rightMouseUp) {
    sound(2).play(member("Click Me"));
}

See also
emulateMultiButtonMouse, Mouse

romanLingo

Usage
the romanLingo

Description
System property; specifies whether Lingo uses a single-byte (TRUE) or double-byte interpreter
(FALSE).

The Lingo interpreter is faster with single-byte character sets. Some versions of Macintosh system
software—Japanese, for example—use a double-byte character set. U.S. system software uses a
single-byte character set. Normally, romanLingo is set when Director is first started and is
determined by the local version of the system software.

If you are using a non-Roman script system but don’t use any double-byte characters in your
script, set this property to TRUE for faster execution of your Lingo scripts.
Example

This statement sets romanLingo to TRUE, which causes Lingo to use a single-byte character set:
set the romanLingo to TRUE

See also
inlineImeEnabled

rootLock

Usage
member(whichCastmember).model(whichModel).keyframePlayer.rootLock
member(whichCastmember).model(whichModel).bonesPlayer.rootLock

Description
3D #keyframePlayer and #bonesPlayer modifier property; indicates whether the translational components of a motion are used (FALSE) or ignored (TRUE).

The default value of this property is FALSE.

Example

This statement forces the model named Alien3 to remain at its starting position while executing its motions, resulting in a character that will walk in place:
member("newalien").model("Alien3").keyframePlayer.rootLock = 1

rootNode

Usage
member(whichCastmember).camera(whichCamera).rootNode
sprite(whichSprite).camera.rootNode

Description
3D property; allows you to get or set which objects are visible within a sprite. When a camera is first created, it shows all nodes within the world. The rootNode property allows you to modify this by creating a different default view that limits what’s shown to a particular node and its children.

For example, light C is a child of model A, if you set the rootNode property to camera("defaultView").rootNode=model(A), the sprite will show only model A as illuminated by light C. The default is group("world"), meaning that all nodes are used.

Example

The following statement sets the rootNode of the camera of sprite 5 to the model Pluto. Only Pluto and its children will be visible in sprite 5.
sprite(5).camera.rootNode = member("Scene").model("Pluto")
rotation

Usage

-- Lingo syntax
spriteObjRef.rotation

// JavaScript syntax
spriteObjRef.rotation;

Description

Sprite property; controls the rotation of a QuickTime movie, animated GIF, Flash movie, or bitmap sprite within a sprite’s bounding rectangle, without rotating that rectangle or the sprite’s controller (in the case of QuickTime). Read/write.

In effect, the sprite’s bounding rectangle acts as a window through which you can see the Flash or QuickTime movie. The bounding rectangles of bitmaps and animated GIFs change to accommodate the rotating image.

Score rotation works for a Flash movie only if obeyScoreRotation is set to TRUE.

A Flash movie rotates around its origin point as specified by its originMode property. A QuickTime movie rotates around the center of the bounding rectangle of the sprite. A bitmap rotates around the registration point of the image.

For QuickTime media, if the sprite’s crop property is set to TRUE, rotating the sprite frequently moves part of the image out of the viewable area; when the sprite’s crop property is set to FALSE, the image is scaled to fit within the bounding rectangle (which may cause image distortion).

You specify the rotation in degrees as a floating-point number.

The Score can retain information for rotating an image from +21,474,836.47° to -21,474,836.48°, allowing 59,652 full rotations in either direction.

When the rotation limit is reached (slightly past the 59,652th rotation), the rotation resets to +116.47° or -116.48°—not 0.00°. This is because +21,474,836.47° is equal to +116.47°, and -21,474,836.48° is equal to -116.48° (or +243.12°). To avoid this reset condition, when you use script to perform continuous rotation, constrain the angles to ±360°.

The default value of this property is 0.

Example

This behavior causes a sprite to rotate continuously by 2° every time the playhead advances, limiting the angle to 360°:

-- Lingo syntax
property spriteNum
on prepareFrame me
    sprite(spriteNum).rotation = integer(sprite(spriteNum).rotation + 2) mod 360
end

// JavaScript syntax
function prepareFrame() {
    sprite(this.spriteNum).rotation = parseInt(sprite(this.spriteNum).rotation + 2) % 360;
}
The following frame script keeps the playhead looping in the current frame while it rotates a QuickTime sprite in channel 5 a full 360° in 16° increments. When the sprite has been rotated 360°, the playhead continues to the next frame.

```lingo
-- Lingo syntax
on rotateMovie(whichSprite)
    repeat with i = 1 to 36
        sprite(whichSprite).rotation = i * 10
        _movie.updateStage()
    end repeat
end
```

```javascript
function rotateMovie(whichSprite) {
    for (var i = 1; i <= 36; i++) {
        sprite(whichSprite).rotation = i * 10;
        _movie.updateStage();
    }
}
```

obeyScoreRotation, originMode, Sprite

rotation (backdrop and overlay)

**Usage**

```plaintext
sprite(whichSprite).camera.backdrop[backdropIndex].rotation
member(whichCastmember).camera(whichCamera).backdrop
[backdropIndex].rotation
sprite(whichSprite).camera.overlay[overlayIndex].rotation
member(whichCastmember).camera[cameraIndex].overlay
[overlayIndex].rotation
```

**Description**

3D property; allows you to get or set the rotation of the backdrop or overlay toward the default camera. The default value of this property is 0.0.

**Example**

This statement rotates a backdrop 60° around its registration point:

```plaintext
sprite(4).camera.backdrop[1].rotation = 60.0
```

See also

bevelDepth, transform (property)
rotation (engraver shader)

Usage

member(whichCastmember).shader(whichShader).rotation
member(whichCastmember).model(whichModel).shader.rotation
member(whichCastmember).model(whichModel).shaderList[index].rotation

Description

3D shader engraver property; allows you to get or set an angle in degrees (as a floating-point number) that describes a 2D rotational offset for engraved lines. The default value for this property is 0.0.

Example

This statement rotates the lines used to draw the engraver shader for the model gbCyl3 by 1°:

member("scene").model("gbCyl3").shader.rotation = \nmember("scene").model("gbCyl3").shader.rotation + 1

See also

transform (property)

rotation (transform)

Usage

member(whichCastmember).node(whichNode).transform.rotation
member(whichCastmember).node(whichNode).getWorldTransform().rotation
transform.rotation

Description

3D property; allows you to get or set the rotational component of a transform. A transform defines a scale, position and rotation within a given frame of reference. The default value of this property is vector(0,0,0).

A node can be a camera, group, light or model object. Setting the rotation of a node's transform defines that object's rotation within the transform's frame of reference. Setting the rotation property of an object's world relative transform using getWorldTransform().rotation defines the object's rotation relative to the world origin. Setting the rotation property of an object's parent relative transform using transform.rotation defines the object's rotation relative to its parent node.

If you wish to modify the orientation of a transform it is recommended that you use the rotate and prerotate methods instead of setting this property.

Example

This statement sets the parent-relative rotation of the first camera in the member to vector(0,0,0):

member("Space").camera[1].transform.rotation = vector(0, 0, 0)
This example displays the parent-relative rotation of the model named Moon, then it adjusts the model's orientation using the rotate command, and finally it displays the resulting world-relative rotation of the model:

```lingo
put member("SolarSys").model("Moon").transform.rotation
   -- vector( 0.0000, 0.0000, 45.0000)
member("SolarSys").model("Moon").rotate(15,15,15)
put member("SolarSys").model("Moon").getWorldTransform().rotation
   --vector( 51.3810, 16.5191, 65.8771 )
```

See also

getWorldTransform(), preRotate, rotate, transform (property), position (transform), scale (transform)

rotationReset

Usage

```lingo
member(whichCastmember).model(whichModel).bonesPlayer.rotationReset
member(whichCastmember).model(whichModel).keyframePlayer.rotationReset
```

Description

3D keyframePlayer and bonesPlayer modifier property; indicates the axes around which rotational changes are maintained from the end of one motion to the beginning of the next, or from the end of one iteration of a looped motion to the beginning of the next iteration.

Possible values of this property include #none, #x, #y, #z, #xy, #yz, #xz, and #all. The default value is #all.

Example

This statement sets the rotationReset property of the model named Monster to the z-axis. The model maintains rotation around its z-axis when the currently playing motion or loop ends.

```lingo
member("NewAlien").model("Monster").bonesPlayer.rotationReset = #z
```

See also

positionReset, bonesPlayer (modifier)

RTF

Usage

```lingo
-- Lingo syntax
memberObjRef.RTF

// JavaScript syntax
memberObjRef.RTF;
```

Description

Cast member property; allows access to the text and tags that control the layout of the text within a text cast member containing text in rich text format.

This property can be tested and set.
Example

This statement displays in the Message window the RTF formatting information embedded in the text cast member Resume:

--Lingo syntax
put(member("Resume").RTF)

// JavaScript syntax
trace(member("Resume").RTF);

See also

HTML, importFileInto()

safePlayer

Usage

-- Lingo syntax
_player.safePlayer

// JavaScript syntax
_player.safePlayer;

Description

Player property; controls whether or not safety features in Director are turned on. Read/write.

In a moview with Shockwave content, this property can be tested but not set. It is always TRUE in Shockwave Player.

In the authoring environment and in projectors, the default value is FALSE. This property may be returned, but it may only be set to TRUE. Once it has been set to TRUE, it cannot be set back to FALSE without restarting Director or the projector.

When safePlayer is TRUE, the following safety features are in effect:

• Only safe Xtra extensions may be used.
• The safePlayer property cannot be reset.
• Pasting content from the Clipboard by using the pasteClipBoardInto() method generates a warning dialog box that allows the user to cancel the operation.
• Saving a movie or cast by using script is disabled.
• Printing by using the printFrom() method is disabled.
• Opening an application by using the open() method is disabled.
• The ability to stop an application or the user's computer by using the restart() or shutDown() methods is disabled.
• Opening a file that is outside the DSWMedia folder is disabled.
• Discovering a local filename is disabled.
• Using getNetText() or postNetText(), or otherwise accessing a URL that does not have the same domain as the movie, generates a security dialog box.

See also

Player
sampleCount

Usage

-- Lingo syntax
soundChannelObjRef.sampleCount

// JavaScript syntax
soundChannelObjRef.sampleCount;

Description

Sound Channel property; specifies the number of sound samples in the currently playing sound in a sound channel. Read-only.

This is the total number of samples, and depends on the sampleRate and duration of the sound. It does not depend on the channelCount of the sound.

A 1-second, 44.1 KHz sound contains 44,100 samples.

Example

This statement displays the name and sampleCount of the cast member currently playing in sound channel 1 in the Message window:

-- Lingo syntax
put("Sound cast member" && sound(1).member.name && "contains" && 
   sound(1).sampleCount && "samples."

// JavaScript syntax
put("Sound cast member " + sound(1).member.name + " contains " + 
   sound(1).sampleCount + " samples.");

See also

sampleRate, Sound Channel

sampleRate

Usage

-- Lingo syntax
soundChannelObjRef.sampleRate

// JavaScript syntax
soundChannelObjRef.sampleRate;

Description

Sound Channel property; returns, in samples per second, the sample rate of the sound cast member or in the case of SWA sound, the original file that has been Shockwave Audio–encoded. Read-only.

This property is available only after the SWA sound begins playing or after the file has been preloaded using the preLoadBuffer() method. When a sound channel is given, the result is the sample rate of the currently playing sound cast member in the given sound channel.

Typical values of this property are 8000, 11025, 16000, 22050, and 44100.
When multiple sounds are queued in a sound channel, Director plays them all with the
channelCount, sampleRate, and sampleSize of the first sound queued, resampling the rest for
smooth playback. Director resets these properties only after the channel's sound queue is
exhausted or a stop() method is issued. The next sound to be queued or played then
determines the new settings.

Example

This statement assigns the original sample rate of the file used in SWA streaming cast member
Paul Robeson to the field cast member Sound Quality:

-- Lingo syntax
member("Sound Quality").text = string(member("Paul Robeson").sampleRate)

// JavaScript syntax
member("Sound Quality").text = member("Paul Robeson").sampleRate.toString();

This statement displays the sample rate of the sound playing in sound channel 1 in the
Message window:

-- Lingo syntax
trace(sound(1).sampleRate)

// JavaScript syntax
trace(sound(1).sampleRate);

See also

channelCount, sampleSize, preLoadBuffer(), Sound Channel, stop() (Sound
Channel)

sampleSize

Usage

-- Lingo syntax
memberObjRef.sampleSize

// JavaScript syntax
memberObjRef.sampleSize;

Description

Cast member property; determines the sample size of the specified cast member. The result is
usually a size of 8 or 16 bits. If a sound channel is given, the value if for the sound member
currently playing in the given sound channel.

This property can be tested but not set.

Example

This statement checks the sample size of the sound cast member Voice Over and assigns the value
to the variable soundSize:

-- Lingo syntax
soundSize = member("Voice Over").sampleSize

// JavaScript syntax
var soundSize = member("Voice Over").sampleSize;
This statement displays the sample size of the sound playing in sound channel 1 in the Message window:

```-- Lingo syntax
put(sound(1).sampleSize)
```
```
// JavaScript syntax
put(sound(1).sampleSize);
```

### scale (3D)

**Usage**

```lxml
member(whichCastmember).camera(whichCamera).backdrop[backdropIndex].scale
member(whichCastmember).camera(whichCamera).overlay[overlayIndex].scale
```

**Description**

3D property; allows you to get or set the scale value used by a specific overlay or backdrop in the referenced camera's list of overlays or backdrops to display. The width and height of the backdrop or overlay are multiplied by the scale value. The default value for this property is 1.0.

**Example**

This statement doubles the size of a backdrop:

```lxml
sprite(25).camera.backdrop[1].scale = 2.0
```

**See also**

`bevelDepth, overlay`

### scale (backdrop and overlay)

**Usage**

```lxml
member(whichCastmember).camera(whichCamera).backdrop[backdropIndex].scale
member(whichCastmember).camera(whichCamera).overlay[overlayIndex].scale
```

**Description**

3D property; allows you to get or set the scale value used by a specific overlay or backdrop in the referenced camera's list of overlays or backdrops to display. The width and height of the backdrop or overlay are multiplied by the scale value. The default value for this property is 1.0.

**Example**

This statement doubles the size of a backdrop:

```lxml
sprite(25).camera.backdrop[1].scale = 2.0
```

**See also**

`bevelDepth, overlay`
scale (Member)

Usage
-- Lingo syntax
memberOrSpriteObjRef.scale

// JavaScript syntax
memberOrSpriteObjRef.scale;

Description
Cast member property and sprite property; controls the scaling of a QuickTime, vector shape, or Flash movie sprite.

For QuickTime, this property does not scale the sprite's bounding rectangle or the sprite's controller. Instead, it scales the image around the image's center point within the bounding rectangle. The scaling is specified as a Director list containing two percentages stored as float-point values:

\[ xPercent, yPercent \]

The \textit{xPercent} parameter specifies the amount of horizontal scaling; the \textit{yPercent} parameter specifies vertical scaling.

When the sprite's \texttt{crop} property is set to \texttt{TRUE}, the \textit{scale} property can be used to simulate zooming within the sprite's bounding rectangle. When the sprite's \texttt{crop} property is set to \texttt{FALSE}, the \textit{scale} property is ignored.

This property can be tested and set. The default value is \([1.0000,1.0000]\).

For Flash movie or vector shape cast members, the scale is a floating-point value. The movie is scaled from its origin point, as specified by its \texttt{originMode} property.

\textbf{Note:} This property must be set to the default value if the \texttt{scaleMode} property is set to \#autoSize; otherwise the sprite does not display correctly.

Example
This handler accepts a reference to a Flash movie sprite as a parameter, reduces the movie's scale to 0% (so it disappears), and then scales it up again in 5% increments until it is full size (100%) again:

\begin{verbatim}
-- Lingo syntax
on scaleMovie whichSprite
    sprite(whichSprite).scale = 0
    _movie.updatestage()
    repeat with i = 1 to 20
        sprite(whichSprite).scale = i * 5
        _movie.updatestage()
    end repeat
end

// JavaScript syntax
function scaleMovie(whichSprite) {
    sprite(whichSprite).scale = 0;
    _movie.updatestage();
    var i = 1;
    while (i < 21) {
        sprite(whichSprite).scale = i * 5;
        _movie.updatestage();
        i++;
    }
}
\end{verbatim}
See also
  scaleMode, originMode

scale (transform)

Usage

member(whichCastmember).node(whichNode).transform.scale
member(whichCastmember).node(whichNode).getWorldTransform().scale
transform.scale

Description

3D property; allows you to get or set the scaling component of a transform. A transform defines a scale, position and rotation within a given frame of reference. The scale property allows you to get and set the degree of scaling of the transform along each of the three axes. The default value of this property is vector(1.0,1.0,1.0).

A node can be a camera, group, light or model object. This command does not have any visual effect on lights or cameras as they do not contain geometry. Setting the scale property of a node's transform defines that object's scaling along the X, Y and Z axes within the transform's frame of reference. Getting the scale property of an object's world relative transform using getWorldTransform().scale returns the object's scaling relative to the world origin. Setting the scale property of an object's parent relative transform using transform.scale defines the object's scaling relative to its parent node.

Example

This statement sets the scale property of the transform of the model named Moon to vector(2,5,3):
member("Scene").model("Moon").transform.scale = vector(2,5,3)

See also
  transform (property), getWorldTransform(), position (transform), rotation (transform), scale (command)

scaleMode

Usage

-- Lingo syntax
memberOrSpriteObjRef.scaleMode

// JavaScript syntax
memberOrSpriteObjRef.setScaleMode;

Description

Cast member property and sprite property; controls the way a Flash movie or vector shape is scaled within a sprite's bounding rectangle. When you scale a Flash movie sprite by setting its scale and viewScale properties, the sprite itself is not scaled; only the view of the movie within the sprite is scaled. The scaleMode property can have these values:

* #showAll (default for Director movies prior to version 7)—Maintains the aspect ratio of the original Flash movie cast member. If necessary, fill in any gap in the horizontal or vertical dimension using the background color.
• **#noBorder**—Maintains the aspect ratio of the original Flash movie cast member. If necessary, crop the horizontal or vertical dimension.

• **#exactFit**—Does not maintain the aspect ratio of the original Flash movie cast member. Stretch the Flash movie to fit the exact dimensions of the sprite.

• **#noScale**—preserves the original size of the Flash media, regardless of how the sprite is sized on the Stage. If the sprite is made smaller than the original Flash movie, the movie displayed in the sprite is cropped to fit the bounds of the sprite.

• **#autoSize** (default)—This specifies that the sprite rectangle is automatically sized and positioned to account for **rotation**, **skew**, **flipH**, and **flipV**. This means that when a Flash sprite is rotated, it will not crop as in earlier versions of Director. The **#autoSize** setting only functions properly when **scale**, **viewScale**, **originPoint**, and **viewPoint** are at their default values.

This property can be tested and set.

**Example**

The following sprite script checks the Stage color of the Director movie and, if the Stage color is indexed to position 0 in the current palette, the script sets the **scaleMode** property of a Flash movie sprite to **#showAll**. Otherwise, it sets the **scaleMode** property to **#noBorder**.

-- Lingo syntax
property spriteNum
on beginsprite me
  if _movie.stage.bgColor = 0 then
    sprite(spriteNum).scaleMode = #showAll
  else
    sprite(spriteNum).scaleMode = #noBorder
  end if
end

// JavaScript syntax
function beginsprite() {
  var stgClr = _movie.stage.bgColor;
  if (stgClr = 0) {
    sprite(this.spriteNum).scaleMode = symbol("showAll");
  } else {
    sprite(this.spriteNum).scaleMode = symbol("noBorder");
  }
}

See also

* scale (Member)*

**SCORE**

**Usage**

-- Lingo syntax
_movie.score

// JavaScript syntax
_movie.score;

**Description**

Movie property; determines which Score is associated with the current movie. Read/write.
This property can be useful for storing the current contents of the Score before wiping out and generating a new one or for assigning the current Score contents to a film loop.

Example
This statement assigns the film loop cast member Waterfall to the Score of the current movie:

-- Lingo syntax
_movie.score = member("Waterfall").media

// JavaScript syntax
_movie.score = member("Waterfall").media;

See also
Movie

scoreColor

Usage
sprite(whichSprite).scoreColor
the scoreColor of sprite whichSprite

Description
Sprite property; indicates the Score color assigned to the sprite specified by whichSprite. The possible values correspond to color chips 0 to 5 in the current palette.

This property can be tested and set. Setting this property is useful only during authoring and Score recording.

Example
This statement displays in the Message window the value for the Score color assigned to sprite 7:

put sprite(7).scorecolor

scoreSelection

Usage
-- Lingo syntax
_movie.scoreSelection

// JavaScript syntax
_movie.scoreSelection;

Description
Movie property; determines which channels are selected in the Score window. Read/write.

The information is formatted as a linear list of linear lists. Each contiguous selection is in a list format consisting of the starting channel number, ending channel number, starting frame number, and ending frame number. Specify sprite channels by their channel numbers; use the following numbers to specify the other channels.

<table>
<thead>
<tr>
<th>To specify</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Frame script channel</td>
<td>0</td>
</tr>
<tr>
<td>Sound channel 1</td>
<td>-1</td>
</tr>
</tbody>
</table>
You can select discontinuous channels or frames.

**Example**

This statement selects sprite channels 15 through 25 in frames 100 through 200:

```-- Lingo syntax
_movie.scoreSelection = [[15, 25, 100, 200]]
```

```// JavaScript syntax
_movie.scoreSelection = list(list(15, 25, 100, 200));
```

This statement selects sprite channels 15 through 25 and 40 through 50 in frames 100 through 200:

```-- Lingo syntax
_movie.scoreSelection = [[15, 25, 100, 200], [40, 50, 100, 200]]
```

```// JavaScript syntax
_movie.scoreSelection = list(list(15, 25, 100, 200), list(40, 50, 100, 200));
```

This statement selects the frame script in frames 100 through 200:

```-- Lingo syntax
_movie.scoreSelection = [[0, 0, 100, 200]]
```

```// JavaScript syntax
_movie.scoreSelection = list(list(0, 0, 100, 200));
```

**See also**

`Movie`
• If `scriptNameOrNum` is an integer, the `script` property provides access only to the script cast member found within the first cast library of the referenced movie; you cannot use indexed access to specify a cast library other than the first one.

Example

The following statement accesses a named script.

-- Lingo syntax
bugScript = _movie.script["Warrior Ant"]

// JavaScript syntax
var bugScript = _movie.script["Warrior Ant"];
**Description**

Player property; returns a linear list of all scripting Xtra extensions available to the Director player. Read-only.

The Xtra extensions are those that are present in the Configuration\Xtras folder.

**Example**

This statement displays in the Message window all available scripting Xtra extensions:

```
-- Lingo syntax
trace(_player.scriptingXtraList)

// JavaScript syntax
trace(_player.scriptingXtraList);
```

**See also**

mediaXtraList, Player, Scripting Objects, toolXtraList, transitionXtraList, xtraList (Player)

---

**scriptInstanceList**

**Usage**

```
sprite(whichSprite).scriptInstanceList
the scriptInstanceList of sprite whichSprite
```

**Description**

Sprite property; creates a list of script references attached to a sprite. This property is available only during run time. The list is empty when the movie is not running. Modifications to the list are not saved in the Score. This property is useful for the following tasks:

- Attaching a behavior to a sprite for use during run time
- Determining if behaviors are attached to a sprite; determining what the behaviors are
- Finding a behavior script reference to use with the `sendSprite` command

This property can be tested and set. (It can be set only if the sprite already exists and has at least one instance of a behavior already attached to it.)

**Example**

This handler displays the list of script references attached to a sprite:

```
on showScriptRefs spriteNum
  put sprite(spriteNum).scriptInstanceList
end
```

These statements attach the script Big Noise to sprite 5:

```
x = script("Big Noise").new()
sprite(5).scriptInstanceList.add(x)
```

**See also**

scriptNum, sendSprite()
scriptList

Usage
sprite(whichSprite).scriptList
the scriptList of sprite whichSprite

Description
Sprite property; returns the list of behaviors attached to the given sprite and their properties. This property may only be set by using setScriptList(). It may not be set during a score recording session.

Example
This statement displays the list of scripts attached to sprite 1 in the Message window:

```lingo
put sprite(1).scriptList
```

```
-- [
  [(member 2 of castLib 1). "[#myRotateAngle: 10.0000, #myClockwise: 1, #myInitialAngle: 0.0000)"],
  [(member 3 of castLib 1). "[#myAnglePerFrame: 10.0000, #myTurnFrames: 10, #myHShiftPerFrame: 10, #myShiftFrames: 10, #myTotalFrames: 60, #mySurfaceHeight: 0)]"
]
```

See also
setScriptList(), value()

scriptNum

Usage
sprite(whichSprite).scriptNum
scriptNum of sprite whichSprite

Description
Sprite property; indicates the number of the script attached to the sprite specified by whichSprite. If the sprite has multiple scripts attached, scriptNum sprite property returns the number of the first script. (To see a complete list of the scripts attached to a sprite, see the behaviors listed for that sprite in the Behavior Inspector.)

This property can be tested and set during Score recording.

Example
This statement displays the number of the script attached to sprite 4:

```lingo
put sprite(4).scriptNum
```

See also
scriptInstanceList

scriptsEnabled

Usage
-- Lingo syntax
memberObjRef.scriptsEnabled

// JavaScript syntax
memberObjRef.scriptsEnabled;
Description

Director movie cast member property; determines whether scripts in a linked movie are enabled (TRUE or 1) or disabled (FALSE or 0).

This property is available for linked Director movie cast members only.

This property can be tested and set.

Example

This statement turns off scripts in the linked movie Jazz Chronicle:

-- Lingo syntax
member("Jazz Chronicle").scriptsEnabled = FALSE

// JavaScript syntax
member("Jazz Chronicle").scriptsEnabled = 0;

scriptText

Usage

-- Lingo syntax
memberObjRef.scriptText

// JavaScript syntax
memberObjRef.scriptText;

Description

Member property; indicates the content of the script, if any, assigned to a cast member.

Read/write.

The text of a script is removed when a movie is converted to a projector, protected, or compressed for Shockwave Player. Such movies then lose their values for the scriptText property. Therefore, the movie's scriptText property values cannot be retrieved when the movie is played back by a projector. However, Director can set new values for the scriptText property inside the projector. These newly assigned scripts are automatically compiled so that they execute quickly.

Example

This statement makes the contents of field cast member 20 the script of cast member 30:

-- Lingo syntax
member(20).text = member(30).scriptText

// JavaScript syntax
member(20).text = member(30).scriptText;

See also

Member
**scriptType**

**Usage**
```plaintext
member whichScript.scriptType
the scriptType of member whichScript
```

**Description**
Cast member property; indicates the specified script's type. Possible values are `#movie`, `#score`, and `#parent`.

**Example**
This statement makes the script member Main Script a movie script:
```plaintext
member("Main Script").scriptType = #movie
```

**scrollTop**

**Usage**
```plaintext
-- Lingo syntax
memberObjRef.scrollTop

// JavaScript syntax
memberObjRef.scrollTop;
```

**Description**
Cast member property; determines the distance, in pixels, from the top of a field cast member to the top of the field that is currently visible in the scrolling box. By changing the value for `scrollTop` member property while the movie plays, you can change the section of the field that appears in the scrolling field.

This is a way to make custom scrolling behaviors for text and field members.

For example, the following Lingo moves the field cast member Credits up or down within a field’s box, depending on the value in the variable `sliderVal`:
```plaintext
global sliderVal

on prepareFrame
  newVal = sliderVal * 100
  member("Credits").scrollTop = newVal
end
```

The global variable `sliderVal` could measure how far the user drags a slider. The statement `set newVal = sliderVal * 100` multiplies `sliderVal` to give a value that is greater than the distance the user drags the slider. If `sliderVal` is positive, the text moves up; if `sliderVal` is negative, the text moves down.
Example

This repeat loop makes the field Credits scroll by continuously increasing the value of scrollTop:

```-Lingo syntax
on wa
  member("Credits").scrollTop = 1
  repeat with count = 1 to 150
    member("Credits").scrollTop = member("Credits").scrollTop + 1
    _movie.updateStage()
  end repeat
end
```

```// JavaScript syntax
function wa() {
  member("Credits").scrollTop = 1;
  for (var count = 1; count <= 150; count++) {
    member("Credits").scrollTop = member("Credits").scrollTop + 1;
    _movie.updateStage();
  }
}
```

sds (modifier)

Usage

```member(whichCastmember).model(whichModel).sds.whichProperty```

Description

3D modifier; adds geometric detail to models and synthesizes additional details to smooth out curves as the model moves closer to the camera. After you have added the sds modifier to a model using addModifier(), you can set the properties of the sds modifier.

The sds modifier directly affects the model resource. Be careful when using the sds and lod modifiers together, because they perform opposite functions (the sds modifier adds geometric detail and the lod modifier removes geometric detail). Before adding the sds modifier, it is recommended that you set the lod.auto modifier property to FALSE and set the lod.level modifier property to the desired resolution, as follows:

```member("myMember").model("myModel").lod.auto = 0
member("myMember").model("myModel").lod.level = 100
member("myMember").model("myModel").addmodifier(#sds)```

The sds modifier cannot be used with models that already use either the inker or toon modifiers.

After you have added the sds modifier to a model resource you can get or set the following properties:

- **enabled** indicates whether subdivision surfaces functionality is enabled (TRUE) or disabled (FALSE). The default setting for this property is TRUE.
- **depth** specifies the maximum number of levels of resolution that the model can display when using the sds modifier.
- **error** indicates the level of error tolerance for the subdivision surfaces functionality. This property applies only when the sds.subdivision property is set to #adaptive.
subdivision indicates the mode of operation of the subdivision surfaces modifier. Possible values are as follows:

- **uniform** specifies that the mesh is uniformly scaled up in detail, with each face subdivided the same number of times.
- **adaptive** specifies that additional detail is added only when there are major face orientation changes and only to those areas of the mesh that are currently visible.

**Note:** For more detailed information about these properties, see the individual property entries.

**Example**

The statement displays the `sds.depth` property value for the model named Terrain:

```
put member("3D").model("Terrain").sds.depth
-- 2
```

**See also**

`lod (modifier), toon (modifier), inker (modifier), depth (3D), enabled (sds), error, subdivision, addModifier`

### searchCurrentFolder

**Usage**

---

**Lingo syntax**

```
_player.searchCurrentFolder
```

**JavaScript syntax**

```
_player.searchCurrentFolder;
```

**Description**

Player property; determines whether Director searches the current folder when searching filenames. Read/write.

- **When** the `searchCurrentFolder` property is **TRUE** (1), Director searches the current folder when resolving filenames.
- **When** the `searchCurrentFolder` property is **FALSE** (0), Director does not search the current folder when resolving filenames.

This property is **TRUE** by default.

**Example**

This statement displays the status of the `searchCurrentFolder` property in the Message window. The result is 1, which is the numeric equivalent of **TRUE**:

```
-- Lingo syntax
put(_player.searchCurrentFolder)

// JavaScript syntax
put(_player.searchCurrentFolder);
```

**See also**

`Player`
searchPathList

Usage

-- Lingo syntax
_player.searchPathList

// JavaScript syntax
_player.searchPathList;

Description

Player property; a list of paths that Director searches when trying to find linked media such as
digital video, GIFs, bitmaps, or sound files. Read/write.

Each item in the list of paths is a fully qualified pathname as it appears on the current platform
at runtime.

The value of searchPathList is a linear list that you can manipulate the same as any other list by
using commands such as add(), addAt(), append(), deleteAt(), and setAt(). The default
value is an empty list.

URLs should not be used as file references in the search paths.

Adding a large number of paths to searchPaths slows searching. Try to minimize the number of
paths in the list.

Note: This property will function on all subsequent movies after being set. Because the current
movie's assets have already been loaded, changing the setting will not affect any of these assets.

Example

This statement displays the paths that Director searches when resolving filenames:

-- Lingo syntax
trace(_player.searchPathList)

// JavaScript syntax
trace(_player.searchPathList);

The following statement assigns two folders to searchPaths in Windows:

-- Lingo syntax
_player.searchPathList = ["C:\Director\Projects", "D:\CDROM\Sources"]

// JavaScript syntax
_player.searchPathList = list("C:\Director\Projects", "D:\CDROM\Sources");

The following statement assigns two folders to searchPaths on a Macintosh:

-- Lingo syntax
_player.searchPathList = ["Hard Drive:Director:Projects:", "CDROM:Sources:"]

// JavaScript syntax
_player.searchPathList = list("Hard Drive:Director:Projects:", "CDROM:Sources");

See also

Player, searchCurrentFolder
selectedButton

Usage
-- Lingo syntax
dvdObjRef.selectedButton

// JavaScript syntax
dvdObjRef.selectedButton;

Description
DVD property; returns the currently active button. Read-only.

See also
DVD

selectedText

Usage
-- Lingo syntax
memberObjRef.selectedText

// JavaScript syntax
memberObjRef.selectedText;

Description
Text cast member property; returns the currently selected chunk of text as a single object reference. This allows access to font characteristics as well as to the string information of the actual characters.

Example
The following handler displays the currently selected text being placed in a local variable object. Then that object is used to reference various characteristics of the text, which are detailed in the Message window.

--Lingo syntax
property spriteNum

on mouseUp(me)
    mySelectionObject = sprite(spriteNum).member.selectedText
    put(mySelectionObject.text)
    put(mySelectionObject.font)
    put(mySelectionObject.fontSize)
    put(mySelectionObject.fontStyle)
end

// JavaScript syntax
function mouseUp() {
    var mySelectionObject = sprite(this.spriteNum).member.selectedText;
    trace(mySelectionObject.text);
    trace(mySelectionObject.font);
    trace(mySelectionObject.fontSize);
    trace(mySelectionObject.fontStyle);
}
selection

Usage

-- Lingo syntax
castObjRef.selection

// JavaScript syntax
castObjRef.selection;

Description

Cast library property; returns the cast members that are selected in a given Cast window. Read/write.

Example

This statement selects cast members 1 through 10 in castLib 1:

-- Lingo syntax
castLib(1).selection = [[1, 10]]

// JavaScript syntax
castLib(1).selection = list( list(1, 10) );

This statement selects cast members 1 through 10, and 30 through 40, in castLib 1:

-- Lingo syntax
castLib(1).selection = [[1, 10], [30, 40]]

// JavaScript syntax
castLib(1).selection = list( list(1, 10), list(30, 40) );

See also

Cast Library

selection (text cast member property)

Usage

member(whichTextMember).selection

Description

Text cast member property; returns a list of the first and last character selected in the text cast member.

This property can be tested and set.

Example

The following statement sets the selection displayed by the sprite of text member myAnswer so that characters 6 through 10 are highlighted:

member("myAnswer").selection = [6, 10]

See also

color(), selStart, selEnd
**selEnd**

**Usage**

```
-- Lingo syntax
selEnd

// JavaScript syntax
selEnd;
```

**Description**

Cast member property; specifies the last character of a selection. It is used with `selStart` to identify a selection in the current editable field, counting from the beginning character.

This property can be tested and set. The default value is 0.

**Example**

These statements select “cde” from the field “abcdefg”:

```
-- Lingo syntax
selStart = 3
selEnd = 5

// JavaScript syntax
selStart = 2;
selEnd = 4;
```

This statement makes a selection 20 characters long:

```
-- Lingo syntax
selEnd = selStart + 20

// JavaScript syntax
selEnd = selStart + 20;
```

**See also**

`editable`, `hilite (command)`, `selection()` (function), `selStart`, `text`

**selStart**

**Usage**

```
-- Lingo syntax
selStart

// JavaScript syntax
selStart;
```

**Description**

Cast member property; specifies the starting character of a selection. It is used with `selEnd` to identify a selection in the current editable field, counting from the beginning character.

This property can be tested and set. The default value is 0.
Example

These statements select "cde" from the field "abcdefg":

```-- Lingo syntax
selStart = 3
selEnd = 5
// JavaScript syntax
selStart = 2;
selEnd = 4;
```

This statement makes a selection 20 characters long:

```-- Lingo syntax
selEnd = selStart + 20
// JavaScript syntax
selEnd = selStart + 20;
```

See also

`selection()` (function), `selEnd`, `text`

serialNumber

Usage

```-- Lingo syntax
_player.serialNumber
// JavaScript syntax
_player.serialNumber;
```

Description

Movie property; a string containing the serial number entered when Director was installed. Read-only.

This property is available in the authoring environment only. It could be used in a movie in a window (MIAW) tool that is personalized to show the user's information.

Example

This handler would be located in a movie script of a MIAW. It places the user's name and the serial number into a display field when the window is opened:

```-- Lingo syntax
on prepareMovie
    displayString = _player.userName & RETURN & _player.organizationName & RETURN & _player.serialNumber
    member("User Info").text = displayString
end

// JavaScript syntax
function prepareMovie() {
    var displayString = _player.userName + "\n" + _player.organizationName + "\n" + _player.serialNumber;
    member("User Info").text = displayString;
}
```

See also

`Player`
shader

Usage

member(whichCastmember).shader(whichShader)
member(whichCastmember).shader[index]
member(whichCastmember).model(whichModel).shader
member(whichCastmember).modelResource(whichModelResource).\
  face[index].shader

Description

3D element, model property, and face property; the object used to define the appearance of the surface of the model. The shader is the “skin” which is wrapped around the model resource used by the model.

The shader itself is not an image. The visible component of a shader is created with up to eight layers of texture. These eight texture layers are either created from bitmap cast members or image objects within Director or imported with models from 3D modeling programs. For more information, see texture.

Every model has a linear list of shaders called the shaderlist. The number of entries in this list equals the number of meshes in the model resource used by the model. Each mesh can be shaded by only one shader.

The 3D cast member has a default shader named DefaultShader, which cannot be deleted. This shader is used when no shader has been assigned to a model and when a shader being used by a model is deleted.

The syntax member(whichCastmember).model(whichModel).shader gives access to the first shader in the model’s shaderlist and is equivalent to member(whichCastmember).model(whichModel).shaderList[1].

Create and delete shaders with the newShader() and deleteShader() commands.

Shaders are stored in the shader palette of the 3D cast member. They can be referenced by name (whichShader) or palette index (shaderIndex). A shader can be used by any number of models. Changes to a shader will appear in all models which use that shader.

There are four types of shaders:

- #standard shaders present their textures realistically.
- #painter, #engraver, and #newsprint shaders stylize their textures for painting, engraving, and newsprint effects. They have special properties in addition to the #standard shader properties.

For more information about shader properties, see the Using Director topics in the Director Help Panel.

The shaders used by individual faces of #mesh primitives can be set with the syntax member(whichCastmember).modelResource(whichModelResource).face[index].shader. Changes to this property require a call to the build() command.
Example

This statement sets the shader property of the model named Wall to the shader named WallSurface:

member("Room").model("Wall").shader = \
member("Room").shader("WallSurface")

See also

shaderList, newShader, deleteShader, face, texture

shaderList

Usage

member(whichCastmember).model(whichModel).shaderList
member(whichCastmember).model(whichModel).shaderList[index]

Description

3D model property; a linear list of shadowPercentage applied to the model. The number of entries in this list equals the number of meshes in the model resource used by the model. Each mesh can be shaded by only one shader.

Set the shader at the specified index position in the shaderList with this syntax:

member(whichCastmember).model(whichModel).shaderList[index] = shaderReference

With 3D text, each character is a separate mesh. Set the value of index to the number of the character whose shader you want to set.

Set all index positions in the shaderList to the same shader with this syntax (note the absence of an index for the shaderList):

member(whichCastmember).model(whichModel).shaderList = shaderReference

Set a property of a shader in the shaderList with this syntax:

member(whichCastmember).model(whichModel).shaderList[index].
  whichProperty = propValue

Set a property of all of the shaders of a model to the same value with this syntax (note the absence of an index for the shaderList):

member(whichCastmember).model(whichModel).shaderList.\n  whichProperty = propValue

Example

This statement sets the second shader in the shaderList of the model named Bumper to the shader named Chrome:

member("Car").model("Bumper").shaderList[2] = \
member("Car").shader("Chrome")

This statement sets the all the shaders in the shaderList of the model named Bumper to the shader named Chrome:

member("Car").model("Bumper").shaderList = \
member("Car").shader("Chrome")

See also

shadowPercentage
shadowPercentage

Usage
member(whichCastmember).model(whichModel).toon.shadowPercentage
member(whichCastmember).model(whichModel).shader.shadowPercentage
member(whichCastmember).shader(whichShader).shadowPercentage

Description
3D toon modifier and painter shader property; indicates the percentage of available colors that are used in the area of the model's surface where light does not create highlights.

The range of this property is 0 to 100, and the default value is 50.

The number of colors used by the toon modifier and painter shader for a model is determined by the colorSteps property of the model's toon modifier or painter shader.

Example
The following statement sets the shadowPercentage property of the toon modifier for the model named Teapot to 50. Half of the colors available to the toon modifier for this model will be used for the shadow area of the model's surface.
member("shapes").model("Teapot").toon.shadowPercentage = 50

See also
colorSteps, shadowStrength

shadowStrength

Usage
member(whichCastmember).model(whichModel).toon.shadowStrength
member(whichCastmember).model(whichModel).shader.shadowStrength
member(whichCastmember).shader(whichShader).shadowStrength

Description
3D toon modifier and painter shader property; indicates the brightness of the area of the model's surface where light does not create highlights.

The default value of this property is 1.0.

Example
The following statement sets the shadowStrength property of the toon modifier for the model named Sphere to 0.1. The area of the model's surface that is not highlighted will be very dark.
member("Shapes").model("Sphere").toon.shadowStrength = 0.1
shapeType

Usage

member(whichCastMember).shapeType
the shapeType of member whichCastMember

Description

Shape cast member property; indicates the specified shape's type. Possible types are #rect, #roundRect, #oval, and #line. You can use this property to specify a shape cast member's type after creating the shape cast member using Lingo.

Example

These statements create a new shape cast member numbered 100 and then define it as an oval:

new(#shape, member 100)
member(100).shapeType = #oval

shiftDown

Syntax

-- Lingo syntax
_key.shiftDown

// JavaScript syntax
_key.shiftDown;

Description

Key property; indicates whether the user is pressing the Shift key. Read-only.

This property returns TRUE if the user is pressing the Shift key; otherwise, it returns FALSE.

This property must be tested in conjunction with another key.

Example

This statement checks whether the Shift key is being pressed and calls the handler doCapitalA if it is:

-- Lingo syntax
if (_key.shiftDown) then
doCapitalA(_key.key)
end if

// JavaScript syntax
if (_key.shiftDown) {
    doCapitalA(_key.key);
}

See also

controlDown, Key, key, keyCode, optionDown
shininess

Usage

member(whichCastmember).shader(whichShader).shininess
member(whichCastmember).model(whichModel).shader.shininess
member(whichCastmember).model(whichModel).shaderList[shaderListIndex].shininess

Description

3D standard shader property; allows you to get or set the shininess of a surface. Shininess is defined as the percentage of shader surface devoted to highlights. The value is an integer between 0 and 100, with a default of 30.

All shaders have access to the #standard shader properties; in addition to these standard shader properties shaders of the types #engraver, #newsprint, and #painter have properties unique to their type. For more information, see newShader.

Example

The following statement sets the shininess property of the first shader in the shader list of the model gbCyl3 to 60. Sixty percent of the surface of the shader will be dedicated to highlights.

member("Scene").model("gbCyl3").shader.shininess = 60

silhouettes

Usage

member(whichCastmember).model(whichModel).inker.silhouettes
member(whichCastmember).model(whichModel).toon.silhouettes

Description

3D toon and inker modifier property; indicates the presence (TRUE) or absence (FALSE) of lines drawn by the modifier at the visible edges of the model.

Silhouette lines are drawn around the model's 2D image on the camera's projection plane. Their relationship to the model's mesh is not fixed, unlike crease or boundary lines, which are drawn on features of the mesh.

Silhouette lines are similar to the lines that outline images in a child's coloring book.

The default value for this property is TRUE.

Example

The following statement sets the silhouettes property of the inker modifier for the model named Sphere to FALSE. Lines will not be drawn around the profile of the model.

member("Shapes").model("Sphere").inker.silhouettes = FALSE
size

Usage

-- Lingo syntax
memberObjRef.size

// JavaScript syntax
memberObjRef.size;

description

Member property; returns the size in memory, in bytes, of a specific cast member. Read-only. Divide bytes by 1024 to convert to kilobytes.

Example

This line outputs the size of the cast member Shrine in a field named How Big:

-- Lingo syntax
member("How Big").text = string(member("shrine").size)

// JavaScript syntax
member("How Big").text = member("shrine").size.toString();

See also

Member

sizeRange

Usage

member(whichCastmember).modelResource
(whichModelResource).sizeRange.start
modelResourceObjectReference.sizeRange.start
member(whichCastmember).modelResource
(whichModelResource).sizeRange.end
modelResourceObjectReference.sizeRange.end

description

3D property; when used with a model resource whose type is #particle, this property allows you to get or set the start and end property of the model resource's sizeRange. Particles are measured in world units.

The size of particles in the system is interpolated linearly between sizeRange.start and sizeRange.end over the lifetime of each particle.

This property must be an integer greater than 0, and has a default value of 1.

Example

In this example, mrFount is a model resource of the type #particle. This statement sets the sizeRange properties of mrFount. The first line sets the start value to 4, and the second line sets the end value to 1. The effect of this statement is that the particles of mrFount are size 4 when they first appear, and gradually shrink to a size of 1 during their lifetime.

member("fountain").modelResource("mrFount").sizeRange.start = 4
member("fountain").modelResource("mrFount").sizeRange.end = 1
sizeState

Usage

-- Lingo syntax
windowObjRef.sizeState

// JavaScript syntax
windowObjRef.sizeState;

Description

Window property; returns the size state of a window. Read-only.

The returned size state will be one of the following values:

<table>
<thead>
<tr>
<th>Size state</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#minimized</td>
<td>Specifies that the window is currently minimized.</td>
</tr>
<tr>
<td>#maximized</td>
<td>Specifies that the window is currently maximized.</td>
</tr>
<tr>
<td>#normal</td>
<td>Specifies that the window is currently neither minimized nor maximized.</td>
</tr>
</tbody>
</table>

Example

These statements maximize the window named Artists if it is not already maximized.

-- Lingo syntax
if (window("Artists").sizeState <> #maximized) then
  window("Artists").maximize()
end if

// JavaScript syntax
if (window("Artists").sizeState != symbol("maximized")) {
  window("Artists").maximize();
}

See also

Window

skew

Usage

-- Lingo syntax
spriteObjRef.skew

// JavaScript syntax
spriteObjRef.skew;

Description

Sprite property; returns, as a float value in hundredths of a degree, the angle to which the vertical edges of the sprite are tilted (skewed) from the vertical. Read/write.

Negative values indicate a skew to the left; positive values indicate a skew to the right. Values greater than 90° flip an image vertically.

The Score can retain information for skewing an image from +21,474,836.47° to -21,474,836.48°, allowing 59,652 full rotations in either direction.
When the skew limit is reached (slightly past the 59,652th rotation), the skew resets to +116.47° or -116.48°—not 0.00°. This is because +21,474,836.47° is equal to +116.47°, and -21,474,836.48° is equal to -116.48° (or +243.12°). To avoid this reset condition, constrain angles to ±360° in either direction when using script to perform continuous skewing.

Example

The following behavior causes a sprite to skew continuously by 2 degrees every time the playhead advances, while limiting the angle to 360 degrees.

-- Lingo syntax
property spriteNum

on prepareFrame me
   sprite(spriteNum).skew = integer(sprite(spriteNum).skew + 2) mod 360
end

// JavaScript syntax
function prepareFrame() {
   sprite(this.spriteNum).skew = parseInt(sprite(this.spriteNum).skew + 2) % 360;
}

See also
flipH, flipV, rotation, Sprite

smoothness

Usage
member(whichTextmember).smoothness
member(whichCastMember).modelResource(whichExtruderModelResource).smoothness

Description
3D extruder model resource and text property; allows you to get or set an integer controlling the number of segments used to create a 3D text cast member. The higher the number, the smoother the text appears. The range of this property is 1 to 10, and the default value is 5.

For more information about working with extruder model resources and text cast members, see extrude3D.

Example

In this example, the cast member Logo is a text cast member. This statement sets the smoothness of Logo to 8. When Logo is displayed in 3D mode, the edges of its letters will be very smooth.
member("Logo").smoothness = 8

In this example, the model resource of the model Slogan is extruded text. This statement sets the smoothness of Slogan's model resource to 1, causing the Slogan's letters to appear very angular.
member("Scene").model("Slogan").resource.smoothness = 1

See also
extrude3D
**sound (Member)**

**Usage**

--- Lingo syntax  
`memberObjRef.sound`

// JavaScript syntax  
`memberObjRef.sound;`

**Description**

Cast member property; controls whether a movie, digital video, or Flash movie’s sound is enabled (TRUE, default) or disabled (FALSE). Read/write.

In Flash members, the new setting takes effect after the currently playing sound ends.

To see an example of `sound` used in a completed movie, see the Sound Control movie in the Learning/Lingo Examples folder inside the Director application folder.

**Example**

This handler accepts a member reference and toggles the member’s `sound` property on or off:

--- Lingo syntax  
```lingo
on ToggleSound(whichMember)
    member(whichMember).sound = not(member(whichMember).sound)
end
```

// JavaScript syntax  
```javascript
function ToggleSound(whichMember) {
    member(whichMember).sound = !(member(whichMember).sound);
}
```

**See also**

Flash Movie

**sound (Player)**

**Usage**

--- Lingo syntax  
`_player.sound[intSoundChannelNum]`

// JavaScript syntax  
`_player.sound[intSoundChannelNum];`

**Description**

Player property; provides indexed access to a Sound Channel object by using a Player property. Read-only.

The `intSoundChannelNum` argument is an integer that specifies the number of the sound channel to access.

The functionality of this property is identical to the top level `sound()` method.
Example

This statement sets the variable mySound to the sound in sound channel 3:

-- Lingo syntax
mySound = _player.sound[3]

// JavaScript syntax
var mySound = _player.sound[3];

See also

Player, sound(), Sound Channel

soundChannel (SWA)

Usage

-- Lingo syntax
memberObjRef.soundChannel

// JavaScript syntax
memberObjRef.soundChannel;

Description

Shockwave Audio (SWA) cast member property; specifies the sound channel in which the SWA sound plays.

If no channel number or channel 0 is specified, the SWA streaming cast member assigns the sound to the highest numbered sound channel that is unused.

Shockwave Audio streaming sounds can appear as sprites in sprite channels, but they play sound in a sound channel. Refer to SWA sound sprites by their sprite channel number, not their sound channel number.

This property can be tested and set.

Example

This statement tells the SWA streaming cast member Frank Zappa to play in sound channel 3:

-- Lingo syntax
member("Frank Zappa").soundChannel = 3

// JavaScript syntax
member("Frank Zappa").soundChannel = 3;
soundChannel (RealMedia)

Usage

-- Lingo syntax
memberOrSpriteObjRef.soundChannel

// JavaScript syntax
memberOrSpriteObjRef.soundChannel;

Description

RealMedia sprite or cast member property; allows you to get or set the sound channel used to play the audio in the RealMedia stream. Setting this property allows you to control the audio of a RealMedia stream using the Lingo sound methods and properties. Setting this property to a value outside the range 0–8 causes a Lingo error. This property has no effect if realPlayerNativeAudio() is set to TRUE.

The default setting for this property is 0, which means that the RealMedia audio will play in the highest sound channel available, and the property's value changes during playback depending on which channel is being used. When the RealMedia cast member is playing, this property reflects the sound channel currently in use. When the RealMedia cast member is stopped, this property reverts to 0.

If you specify a channel (1–8) for this property and there are sounds currently playing in that channel (from other parts of the movie), they will be stopped and the RealMedia audio will play in the channel instead.

Concurrently playing RealMedia cast members are not supported; if your movie contains RealMedia cast members that play concurrently, their sounds are played simultaneously in the same sound channel.

Example

The following examples show that the sound in the RealMedia stream in sprite 2 and the cast member Real will be played in sound channel 2.

-- Lingo syntax
put(sprite(2).soundChannel) -- 2
put(member("Real").soundChannel) -- 2

// JavaScript syntax
put(sprite(2).soundChannel); // 2
put(member("Real").soundChannel); // 2

The following examples assign sound channel 1 to the RealMedia stream in sprite 2 and the cast member Real.

-- Lingo syntax
sprite(2).soundChannel = 1
member("Real").soundChannel = 1

// JavaScript syntax
sprite(2).soundChannel = 1;
member("Real").soundChannel = 1;

See also

realPlayerNativeAudio()
**soundDevice**

**Usage**

--- Lingo syntax
_sound.soundDevice

// JavaScript syntax
_sound.soundDevice;

**Description**

Sound property; allows the sound mixing device to be set while the movie plays. Read/write. The possible settings for `soundDevice` are the devices listed in `soundDeviceList`.

Several sound devices can be referenced. The various sound devices for Windows have different advantages.

- **MacroMix (Windows)**—The lowest common denominator for Windows playback. This device functions on any Windows computer, but its latency is not as good as that of other devices.
- **QT3Mix (Windows)**—Mixes sound with QuickTime audio and possibly with other applications if they use DirectSound. This device requires that QuickTime be installed and has better latency than MacroMix.
- **DirectSound (Windows)**—Similar to QT3Mix, but provides higher latency.
- **MacSoundManager (Macintosh)**—The only sound device available on the Macintosh.

**Example**

The following statement sets the sound device to the MacroMix for a Windows computer. If the newly assigned device fails, the `soundDevice` property is not changed.

--- Lingo syntax
_sound.soundDevice = "MacroMix"

// JavaScript syntax
_sound.soundDevice = "MacroMix";

**See also**

`Sound`, `soundDeviceList`

**soundDeviceList**

**Usage**

--- Lingo syntax
_sound.soundDeviceList

// JavaScript syntax
_sound.soundDeviceList;

**Description**

Sound property; creates a linear list of sound devices available on the current computer. Read-only.

For the Macintosh, this property lists one device, MacSoundManager.
Example

This statement displays a typical sound device list on a Windows computer:

-- Lingo syntax
trace(_sound.soundDeviceList)

// JavaScript syntax
trace(_sound.soundDeviceList);

See also

Sound, soundDevice

soundEnabled

Usage

-- Lingo syntax
_sound.soundEnabled

// JavaScript syntax
_sound.soundEnabled;

Description

Sound property; determines whether the sound is on (TRUE, default) or off (FALSE). Read/write.

When you set this property to FALSE, the sound is turned off, but the volume setting is not changed.

Example

This statement sets soundEnabled to the opposite of its current setting; it turns the sound on if it is off and turns it off if it is on:

-- Lingo syntax
_sound.soundEnabled = not(_sound.soundEnabled)

// JavaScript syntax
_sound.soundEnabled = !(_sound.soundEnabled);

See also

Sound

soundKeepDevice

Usage

-- Lingo syntax
_sound.soundKeepDevice

// JavaScript syntax
_sound.soundKeepDevice;

Description

Sound property; for Windows only, determines whether the sound driver unloads and reloads each time a sound needs to play. Read/write.

The default value of this property is TRUE, which prevents the sound driver from unloading and reloading each time a sound needs to play.
You may need to set this property to FALSE before playing a sound to ensure that the sound device is unloaded and made available to other applications or processes on the computer after the sound has finished.

Setting this property to FALSE may adversely affect performance if sound playback is used frequently throughout the Director application.

Example

This statement sets the soundKeepDevice property to FALSE:

```-- Lingo syntax
_sound.soundKeepDevice = FALSE
// JavaScript syntax
_sound.soundKeepDevice = false;
```

See also

Sound

**soundLevel**

**Usage**

```-- Lingo syntax
_sound.soundLevel
// JavaScript syntax
_sound.soundLevel;
```

**Description**

Sound property; returns or sets the volume level of the sound played through the computer’s speaker. Read/write.

Possible values range from 0 (no sound) to 7 (the maximum, default).

In Windows, the system sound setting combines with the volume control of the external speakers. Thus, the actual volume that results from setting the sound level can vary. Avoid setting the soundLevel property unless you are sure that the result is acceptable to the user. It is better to set the individual volumes of the channels and sprites with the Sound Channel object's volume property.

These values correspond to the settings in the Macintosh Sound control panel. Using this property, script can change the sound volume directly or perform some other action when the sound is at a specified level.

To see an example of soundLevel used in a completed movie, see the Sound Control movie in the Learning/Lingo Examples folder inside the Director application folder.

Example

This statement sets the variable oldSound equal to the current sound level:

```-- Lingo syntax
oldSound = _sound.soundLevel
// JavaScript syntax
var oldSound = _sound.soundLevel;
```
This statement sets the sound level to 5:

-- Lingo syntax
_sound.soundLevel = 5

// JavaScript syntax
_sound.soundLevel = 5;

See also
Sound, volume (Windows Media)

soundMixMedia

Usage

-- Lingo syntax
_sound.soundMixMedia

// JavaScript syntax
_sound.soundMixMedia;

Description

Sound property; determines whether Flash cast members will mix their sound with sounds in the Score sound channels. Read/write.

This property defaults to TRUE for movies made with Director 7 and later and FALSE for earlier ones. It is also valid only on Windows.

When this property is TRUE, Flash cast members will mix their sound with sounds in the Score sound channels. Director takes over the mixing and playback of sounds from Flash cast members.

It is possible that slight differences may occur in the way Flash sounds play back. To hear the Flash sounds exactly they would be rendered in Flash, set this property to FALSE.

When this property is set to FALSE, Flash sounds will not be mixed and must be played at separate times.

See also
Sound

source

Usage

sprite(whichSprite).camera.backdrop[backdropIndex].source
member(whichCastmember).camera(whichCamera).backdrop
[backdropIndex].source
sprite(whichSprite).camera.overlay[overlayIndex].source
member(whichCastmember).camera(whichCamera).overlay
[overlayIndex].source

Description

3D backdrop and overlay property; allows you to get or set the texture to use as the source image for the overlay or backdrop.
Example
This statement sets the source of backdrop 1 to the texture Cedar:

```lingo
sprite(3).camera.backdrop[1].source = sprite(3).member.texture("Cedar")
```

See also
bevelDepth, overlay

coresourceFileName

Usage
```
FlashCastMember.coresourceFileName
```

Description
Flash cast member property; specifies the pathname of the FLA source file to be used during launch-and-edit operations. This property can be tested and set. The default is an empty string.

Example
This Lingo sets the `coresourceFileName` of the Flash cast member “SWF” to `C:\FlashFiles\myFile.fla`:

```lingo
member("SWF").coresourceFileName = "C:\FlashFiles\myFile.fla"
```

coresourceRect

Usage
```
-- Lingo syntax
windowObjRect.coresourceRect

// JavaScript syntax
windowObjRect.coresourceRect;
```

Description
Window property; specifies the original Stage coordinates of the movie playing in a window. Read-only.

This property is useful for returning a window to its original size and position after it has been dragged or its rectangle has been set.

Example
This statement displays the original coordinates of the Stage named Control_panel in the Message window:

```lingo
-- Lingo syntax
put(window("Control_panel").coresourceRect)

// JavaScript syntax
put(window("Control_panel").coresourceRect);
```

See also
Window
specular (light)

**Usage**

```csharp
member(whichCastmember).light(whichLight).specular
```

**Description**

3D light property; allows you to get or set whether specularity is on (TRUE) or off (FALSE).
Specularity refers to the ability to have a highlight appear on a model where the light hitting the model is reflected toward the camera. The shininess of the model's shader determines how large the specular portion of the highlight is. The value for this property is ignored for ambient lights.

The default value for this property is TRUE.

*Note:* Turning off this property may increase performance.

**Example**

The following statement sets the specular property of the light omni2 to FALSE. This light does not cause highlights. If this is the only light currently shining in the scene, there will be no specular highlights on any of the shaders in the scene.

```csharp
member("3d world").light("omni2").specular = FALSE
```

**See also**

silhouettes, specularLightMap

specular (shader)

**Usage**

```csharp
member(whichCastmember).shader(whichShader).specular
```

**Description**

3D standard shader property; allows you get or set the specular color of a given shader. The specular color is the color of the highlight generated when specularity is turned on. There must be lights in the scene with the specular property set to TRUE, for this property to have a visible effect.

The specular color is influenced by the color of the lights illuminating the object. If the specular color is white but the color of a light is red, there will be a red specular highlight appearing on the object. The default value for this property is rgb(255, 255, 255) which is white.

All shaders have access to the #standard shader properties; in addition to these standard shader properties shaders of the types #engraver, #newsprint, and #painter have properties unique to their type. For more information, see newShader.

**Example**

```csharp
put member("scene").shader("plutomat").specular
  -- rgb(11, 11, 11)
```

**See also**

silhouettes, specular (light), specularColor, emissive
specularColor

Usage

member(whichCastmember).specularColor

Description

3D cast member property; allows you to get or set the RGB value of the specular color of the first shader in the cast member. The first shader in the cast member's shader palette is always the default shader. This and all other 3D cast member properties are saved with the cast member and are restored the next time you open the movie. The default value for this property is rgb(255, 255, 255) which is white.

Example

The following statement sets the specular color of the first shader in the cast member Scene to rgb(255, 0, 0). It is equivalent to member("Scene").shader[1].specular = rgb(255, 0, 0). However, that syntax won't save the new value with the cast member when the movie is saved. Only member.specularColor will save the new color value.

member("Scene").specularColor = rgb(255, 0, 0)

See also

silhouettes, specular (light), specular (shader)

specularLightMap

Usage

member(whichCastmember).shader(whichShader).specularLightMap
member(whichCastmember).model(whichModel).shader.specularLightMap
member(whichCastmember).model(whichModel).shaderList[shaderListIndex].specularLightMap

Description

3D standard shader property; allows you to get or set the fifth texture layer of a given standard shader. This property is ignored if the toon modifier is applied to the model resource.

The values that can be set are as follows:

- textureModeList[5] = #specular
- blendFunctionList[5] = #add
- blendFunctionList[1] = #replace
- default = void

This helper property provides a simple interface for setting up a common use of specular light mapping.

All shaders have access to the #standard shader properties; in addition to these standard shader properties shaders of the types #engraver, #newsprint, and #painter have properties unique to their type. For more information, see the newShader.
Example
This statement sets the texture Oval as the specularLightMap of the shader used by the model GlassBox:

```plaintext
member("3DPlanet").model("GlassBox").shader.specularLightMap = \
  member("3DPlanet").texture("Oval")
```

See also
diffuseLightMap

spotAngle

Usage

```plaintext
member(whichCastmember).light(whichLight).spotAngle
```

Description

3D property; allows you to get or set the angle of the light projection cone. Light that is falls outside of the angle specified for this property, contributes no intensity. This property takes float value between 0.0 and 180.00, and has a default value of 90.0. The float value you specify corresponds to half the angle; for instance if you wish to specify a 90° angle you would pass a value of 45.0.

Example

This statement sets the spotAngle property of the light unidirectional to 8. The angle of the light projection cone will be 16°:

```plaintext
member("3d world").light("unidirectional").spotAngle = 8
```

spotDecay

Usage

```plaintext
member(whichCastmember).light(whichLight).spotDecay
```

Description

3D light property; allows you get or set whether a spotlight’s intensity falls off with the distance from the camera. The default value for this property is FALSE.

Example

The following statement sets the spotDecay property of light 1 to TRUE. Models that are farther away from light 1 will be less brightly lit than models that are closer to it.

```plaintext
member("Scene").light[1].spotDecay = TRUE
```
sprite (Movie)

Usage

-- Lingo syntax
_movie.sprite[spriteNameOrNum]

// JavaScript syntax
_movie.sprite[spriteNameOrNum];

Description

Movie property; provides indexed or named access to a movie sprite. Read-only.

The spriteNameOrNum argument can be either a string that specifies the name of the sprite or an integer that specifies the number of the sprite.

Example

The following statement sets the variable sportSprite to the movie sprite 5:

-- Lingo syntax
sportSprite = _movie.sprite[5]

// JavaScript syntax
var sportSprite = _movie.sprite[5];

See also

Movie

sprite (Sprite Channel)

Usage

-- Lingo syntax
spriteChannelObjRef.sprite

// JavaScript syntax
spriteChannelObjRef.sprite;

Description

Sprite Channel property; returns a reference to the sprite in the current frame of a sprite channel. Read-only.

Example

This statement sets the variable mySprite to the sprite in the sprite channel named Ribbon.

-- Lingo syntax
mySprite = channel("Ribbon").sprite

// JavaScript syntax
var mySprite = channel("Ribbon").sprite;

See also

Sprite Channel
spriteNum

Usage

-- Lingo syntax
spriteObjRef.spriteNum

// JavaScript syntax
spriteObjRef.spriteNum;

Description

Sprite property; determines the channel number the behavior’s sprite is in and makes it available to any behaviors. Read-only.

Simply declare the property at the top of the behavior, along with any other properties the behavior may use.

If you use a new() handler to create an instance of the behavior, the script’s new() handler must explicitly set the spriteNum property to the sprite’s number. This provides a way to identify the sprite the script is attached to. The sprite’s number must be passed to the new() handler as an argument when the new() handler is called.

Example

In this handler, the spriteNum property is automatically set for script instances that are created by the system:

-- Lingo syntax
property spriteNum, pMySpriteRef

on mouseDown me
  sprite(spriteNum).member = member("DownPict")
end

// JavaScript syntax
function mouseDown() {
  sprite(this.spriteNum).member = member("DownPict");
}

This handler uses the automatic value inserted into the spriteNum property to assign the sprite reference to a new property variable pMySpriteRef, as a convenience:

-- Lingo syntax
property spriteNum, pMySpriteRef

on beginSprite me
  pMySpriteRef = sprite(me.spriteNum)
end

// JavaScript syntax
function beginSprite() {
  this.pMySpriteRef = sprite(this.spriteNum);
}
This approach allows the use of the reference `pMySpriteRef` later in the script, with the handler using the syntax:

```-- Lingo syntax
currMember = pMySpriteRef.member
// JavaScript syntax
var currMember = pMySpriteRef.member
```

instead of the following syntax which is somewhat longer:

```-- Lingo syntax
currMember = sprite(spriteNum).member
// JavaScript syntax
var currMember = sprite(this.spriteNum).member
```

This alternative approach is merely for convenience, and provides no different functionality.

**See also**

`new()`, `Sprite`

---

**stage**

**Usage**

```-- Lingo syntax
_movie.stage
// JavaScript syntax
_movie.stage;
```

**Description**

Movie property; refers to the main movie. Read-only.

This property is useful when sending a message to the main movie from a child movie.

**Example**

This statement displays the current setting for the Stage:

```-- Lingo syntax
put(_movie.stage.rect)
// JavaScript syntax
put(_movie.stage.rect);
```

**See also**

`Movie`
**startAngle**

**Usage**

```lingo
member(whichCastmember).modelResource(whichModelResource).
startAngle
modelResourceObjectReference.startAngle
```

**Description**

3D property; when used with a model resource whose type is `#cylinder` or `#sphere`, this command allows you to both get and set the `startAngle` property of the referenced model resource, as a floating-point value from 0.0 to 360.0. The default value for this property is 0.0.

The `startAngle` property determines the starting sweep angle of the model resource, and works in conjunction with the `endAngle` property to draw spheres and cylinders. For example, if you want to make a half sphere, set `startAngle` to 0.0 and `endAngle` to 180.0.

**Example**

The following statement sets the `startAngle` of the model resource `Sphere01` to 0.0. If its `endAngle` is set to 90, then only one quarter of any model that uses this model resource will appear.

```lingo
put member("3D World").modelResource("Sphere01").startAngle
-- 0.0
```

**See also**

`endAngle`

---

**startFrame**

**Usage**

```lingo
-- Lingo syntax
spriteObjRef.startFrame
```

```javascript
// JavaScript syntax
spriteObjRef.startFrame;
```

**Description**

Sprite property; returns the frame number of the starting frame of a sprite span. Read-only.

This property is useful in determining the span in the Score that a particular sprite covers. It is available only in a frame that contains the sprite, and cannot be applied to sprites in different frames of the movie.

**Example**

This statement displays the starting frame of the sprite in channel 5 in the Message window:

```lingo
-- Lingo syntax
put(sprite(5).startFrame)
```

```javascript
// JavaScript syntax
put(sprite(5).startFrame);
```

**See also**

`endFrame`, `Sprite`
startTime

Usage

-- Lingo syntax
soundChannelObjRef.startTime

// JavaScript syntax
soundChannelObjRef.startTime;

Description

Sound Channel property; indicates the start time of the currently playing or paused sound as set when the sound was queued. Read-only.

This property cannot be set after the sound has been queued. If no value was supplied when the sound was queued, this property returns 0.

Example

This statement starts the digital video sprite in channel 5 at 100 ticks into the digital video:

-- Lingo syntax
sprite(5).startTime = 100

// JavaScript syntax
sprite(5).startTime = 100;

See also

Sound Channel

startTimeList

Usage

-- Lingo syntax
dvdObjRef.startTimeList

// JavaScript syntax
dvdObjRef.startTimeList;

Description

DVD property; a property list that specifies the time or chapter at which playback starts. Read/write.

A startTimeList is a property list that can be either chapter based or time based.

A chapter-based startTimeList contains the following properties:

• title. Specifies the title that contains the chapter to play.
• chapter. Specifies the chapter to play.

A time-based startTimeList contains the following properties:

• title. Specifies the title.
• hours. Specifies the hour at which playback starts.
• min. Specifies the minute at which playback starts.
• sec. Specifies the second at which playback starts.
frames. Specifies the frames at which playback starts.
The startTimeList can be cleared by setting it to 0.

Example
This startTimeList starts playing at chapter 4 of title 1:
[#title:1, #chapter:4]
This startTimeList starts playing at a specific time in title 1:
[#title:1, #hours:0, #minutes:55, #seconds:45, #frames:15]
This startTimeList only lists one time parameter:
[#title:1, #seconds:45]

See also
DVD

state (3D)

Usage
member(whichCastmember).state

Description
3D property; returns the current state of the referenced member in the streaming and loading process. This property refers to the initial file import or the last file load requested.
The state property of the member determines what, if any, 3D Lingo can be performed on the cast member.

This property can have any of the following values:
• 0—indicates that the member is currently not loaded and therefore no 3D media are available. No 3D Lingo should be performed on the member.
• 1—indicates that the media loading has begun.
• 2—indicates that the member’s initial load segment is loaded. All objects with a stream priority of zero, as set upon creation of the model file, will be loaded at this time, because they are part of the initial load segment. You can perform most 3D Lingo associated with objects that have a load priority of zero. Do not use the loadFile and resetWorld commands during this state.
• 3—indicates that all the additional media of the member are being loaded and decompressed. Most 3D Lingo can be performed at this point. Do not use the loadFile and resetWorld commands during this state.
• 4—indicates that all of the member’s media have been loaded and all decompression is complete. All 3D Lingo can now be performed on the cast member.
• -1—indicates that an undefined error occurred during the media streaming process. Because the error may have occurred at any point during the loading process, the state of the cast member is not reliable.

In general, avoid using Lingo on 3D cast members with a current state lower than 3.
Example

This statement shows that the cast member named PartyScene has finished loading and preparing for playback, and no errors occurred during the load:

```
put member("PartyScene").state
-- 4
```

`state` *(Flash, SWA)*

**Usage**

```Lingo syntax
memberObjRef.state
```

```JavaScript syntax
memberObjRef.state;
```

**Description**

Cast member property; for Shockwave Audio (SWA) streaming cast members and Flash movie cast members, determines the current state of the streaming file. The properties `streamName`, `URL`, and `preloadTime` can be changed only when the SWA sound is stopped.

The following properties for the SWA file return meaningful information only after the file begins streaming: `cuePointNames`, `cuePointTimes`, `currentTime`, `duration`, `percentPlayed`, `percentStreamed`, `bitRate`, `sampleRate`, and `numChannels`.

For SWA streaming cast members, the following values are possible:

- 0—Cast streaming has stopped.
- 1—The cast member is reloading.
- 2—Preloading ended successfully.
- 3—The cast member is playing.
- 4—The cast member is paused.
- 5—The cast member has finished streaming.
- 9—An error occurred.
- 10—There is insufficient CPU space.

For Flash movie cast members, this property returns a valid value only when the Director movie is running. The following values are possible:

- 0—The cast member is not in memory.
- 1—The header is currently loading.
- 2—The header has finished loading.
- 3—The cast member’s media is currently loading.
- 4—The cast member’s media has finished loading.
- -1—An error occurred.

This property can be tested but not set.
Example

This statement issues an alert if an error is detected for the SWA streaming cast member:

```-- Lingo syntax
on mouseDown
    if member("Ella Fitzgerald").state = 9 then
        _player.alert("Sorry, can't find an audio file to stream.");
    end if
end

// JavaScript syntax
function mouseDown() {
    var ellaSt = member("Ella Fitzgerald").state;
    if (ellaSt == 9) {
        _player.alert("Sorry, can't find an audio file to stream.");
    }
}
```

Example

The following frame script checks to see if a Flash movie cast member named Intro Movie has finished streaming into memory. If it hasn't, the script reports in the Message window the current state of the cast member and keeps the playhead looping in the current frame until the movie finishes loading into memory.

```-- Lingo syntax
on exitFrame
    if member("Intro Movie").percentStreamed < 100 then
        put("Current download state: " & member("Intro Movie").state); _movie.go(_movie.frame)
    end if
end

// JavaScript syntax
function exitFrame() {
    var intSt = member("Intro Movie").percentStreamed;
    if (intSt < 100) {
        put("Current download state: " + member("Intro Movie").state); _movie.go(_movie.frame);
    }
}
```

See also

clearError(), getError() (Flash, SWA)

state (RealMedia)

Usage

```-- Lingo syntax
memberOrSpriteObjRef.state

// JavaScript syntax
memberOrSpriteObjRef.state;
```

Description

RealMedia sprite or cast member property; returns the current state of the RealMedia stream, expressed as an integer in the range 1 to 4. Each state value corresponds to a specific point in the streaming process. This property is dynamic during playback and can be tested but not set.
The streaming process is initiated when the playhead enters the span of the RealMedia sprite in the Score, the play method is invoked on a RealMedia sprite or cast member, or a user clicks the Play button in the RealMedia viewer. Calling this property returns a numeric value indicating the state of the streaming process for the RealMedia cast member. For each state, there is one or more corresponding mediaStatus (RealMedia, Windows Media) property value; each mediaStatus value is observed only in one state. For example, the mediaStatus property values #seeking and #buffering are present only when the value of state is 3.

The value of the state property provides important information in terms of performing Lingo on a cast member. If member.state is less than 2, some of the Lingo properties may be incorrect, and as a result, any Lingo relying on property data would be incorrect. When member.state is greater than or equal to 2 and less than 4, the RealMedia cast member is not displayed, but all the Lingo properties and methods have well-defined values and can be used to perform Lingo operations on the cast member.

When the streaming process is initiated, the state property cycles through the following states, unless an error (-1) occurs, which prevents the streaming process from starting:

-1 (error) indicates that there is something wrong, possibly a leftover error from the previous RealMedia stream. You may get more information by checking the lastError property. This state is the equivalent of #error for the mediaStatus property.

0 (closed) indicates that streaming has not begun, or that cast member properties are in initial states or are copies from an earlier playing of the cast member. This state is the equivalent of #closed for the mediaStatus property.

1 (connecting) indicates that streaming has begun but is in the very early stages of connecting to the server, and there is not enough information available locally to do anything with the cast member. This state is the equivalent of #connecting for the mediaStatus property.

2 (open) indicates that the Lingo properties have been refreshed from the actual stream. When state is greater than or equal to 2, the height, width, and duration properties of the RealMedia stream are known. This state is transitory and quickly changes to state 3. This state is the equivalent of #opened for the mediaStatus property.

3 (seeking or buffering) indicates that all of the RealMedia cast member's Lingo properties are current, but the cast member is not quite ready to play. The Stage or RealMedia viewer displays a black rectangle or the RealNetworks logo. If this state is the result of rebuffering due to network congestion, the state value quickly changes back to 4 (playing). This state is the equivalent of #buffering or #seeking for the mediaStatus property.

4 (playing) indicates that the RealMedia stream is playing (or paused) without problems or errors. This is the state during normal playback. This state is the equivalent of #playing or #paused for the mediaStatus property.

Example

The following examples show that the state of streams in sprite 2 and the cast member Real is 0, which is closed:

-- Lingo syntax
put(sprite(2).state) -- 0
put(member("Real").state) -- 0

// JavaScript syntax
put(sprite(2).state); // 0
put(member("Real").state); // 0
See also
mediaStatus (RealMedia, Windows Media), percentBuffered, lastError

static

Usage
-- Lingo syntax
memberOrSpriteObjRef.static

// JavaScript syntax
memberOrSpriteObjRef.static;

Description
Cast member property and sprite property; controls playback performance of a Flash movie sprite depending on whether the movie contains animation. If the movie contains animation (FALSE, default), the property redraws the sprite for each frame; if the movie doesn't contain animation (TRUE), the property redraws the sprite only when it moves or changes size.

This property can be tested and set.

Note: Set the static property to TRUE only when the Flash movie sprite does not intersect other moving Director sprites. If the Flash movie intersects moving Director sprites, it may not redraw correctly.

Example
This sprite script displays in the Message window the channel number of a Flash movie sprite and indicates whether the Flash movie contains animation:

-- Lingo syntax
property spriteNum
on beginSprite me
if sprite(spriteNum).static then
  animationType = "does not have animation."
else
  animationType = "has animation."
end if
put("The Flash movie in channel" && spriteNum && animationType)
end

// JavaScript syntax
function beginSprite() {
  var st = sprite(this.spriteNum).static;
  if (st = 1) {
    animationType = "does not have animation."
  } else {
    animationType = "has animation."
  }
  trace("The Flash movie in channel " + this.spriteNum + animationType);
}
staticQuality

Usage
-- Lingo syntax
spriteObjRef.staticQuality

// JavaScript syntax
spriteObjRef.staticQuality;

Description
QuickTime VR sprite property; specifies the codec quality used when the panorama image is static. Possible values are #minQuality, #maxQuality, and #normalQuality. This property can be tested and set.

status

Usage
-- Lingo syntax
soundChannelObjRef.status

// JavaScript syntax
soundChannelObjRef.status;

Description
Sound Channel property; indicates the status of a sound channel. Read-only. Possible values include:

<table>
<thead>
<tr>
<th>Status</th>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Idle</td>
<td>No sounds are queued or playing.</td>
</tr>
<tr>
<td>1</td>
<td>Loading</td>
<td>A queued sound is being preloaded but is not yet playing.</td>
</tr>
<tr>
<td>2</td>
<td>Queued</td>
<td>The sound channel has finished preloading a queued sound but is not yet playing the sound.</td>
</tr>
<tr>
<td>3</td>
<td>Playing</td>
<td>A sound is playing.</td>
</tr>
<tr>
<td>4</td>
<td>Paused</td>
<td>A sound is paused.</td>
</tr>
</tbody>
</table>

Example
This statement displays the current status of sound channel 2 in the Message window:

-- Lingo syntax
put(sound(2).status)

// JavaScript syntax
put(sound(2).status);

See also
Sound Channel
stillDown

Usage

-- Lingo syntax
_mouse.stillDown

// JavaScript syntax
_mouse.stillDown;

Description

Mouse property; indicates whether the user is pressing the mouse button (TRUE) or not (FALSE). Read-only.

This function is useful within a mouseDown script to trigger certain events only after the mouseUp function.

Script cannot test stillDown when it is used inside a loop. Use the mouseDown function inside loops instead.

Example

This statement checks whether the mouse button is being pressed and calls the handler dragProcedure if it is:

-- Lingo syntax
if (_mouse.stillDown) then
   dragProcedure
end if

// JavaScript syntax
if (_mouse.stillDown) {
   dragProcedure();
}

See also

Mouse, mouseDown, mouseUp

stopTime

Usage

sprite(whichSprite).stopTime

the stopTime of sprite whichSprite

Description

Sprite property; determines when the specified digital video sprite stops. The value of stopTime is measured in ticks.

This property can be tested and set.

Example

This statement stops the digital video sprite in channel 5 at 100 ticks into the digital video:
sprite(5).stopTime = 100
stopTimeList

Usage

-- Lingo syntax
dvdObjRef.stopTimeList

// JavaScript syntax
dvdObjRef.stopTimeList;

Description

DVD property; a property list that specifies the time or chapter at which playback stops. Read/write.

A stopTimeList is a property list that can be either chapter based or time based.

A chapter-based stopTimeList contains the following properties:

• title. Specifies the title.
• chapter. Specifies the chapter. Playback stops after the chapter is played.

A time-based stopTimeList contains the following properties:

• title. Specifies the title.
• hours. Specifies the hour at which playback stops.
• min. Specifies the minute at which playback stops.
• sec. Specifies the second at which playback stops.
• frames. Specifies the frames at which playback stops.

The stopTimeList can be cleared by setting it to 0.

Example

This stopTimeList stops playing at chapter 4 of title 1:
[#title:1, #chapter:4]

This stopTimeList stops playing at a specific time in title 1:
[#title:1, #hours:0, #minutes:55, #seconds:45, #frames:15]

This stopTimeList only lists one time parameter:
[#title:1, #seconds:45]

See also

DVD

streamMode

Usage

-- Lingo syntax
memberObjRef.streamMode

// JavaScript syntax
memberObjRef.streamMode;
streamName

Usage

-- Lingo syntax
memberObjRef.streamName

// JavaScript syntax
memberObjRef.streamName;

Description

Shockwave Audio (SWA) cast member property; specifies a URL or filename for a streaming cast member. This property functions the same as the URL member property.

This property can be tested and set.
Example

The following statement links the file BigBand.swa to an SWA streaming cast member. The linked file is on the disk MyDisk in the folder named Sounds.

-- Lingo syntax
member("SWAstream").streamName = "MyDisk/sounds/BigBand.swa"

// JavaScript syntax
member("SWAstream").streamName = "MyDisk/sounds/BigBand.swa";

streamSize

Usage

-- Lingo syntax
memberObjRef.streamSize

// JavaScript syntax
memberObjRef.streamSize;

Description

Cast member property; reports an integer value indicating the total number of bytes in the stream for the specified cast member. The streamSize property returns a value only when the Director movie is playing.

This property can be tested but not set.

Example

The following frame script checks to see if a Flash movie cast member named Intro Movie has finished streaming into memory. If it hasn’t, the script updates a field cast member to indicate the number of bytes that have been streamed (using the bytesStreamed member property) and the total number of bytes for the cast member (using the streamSize member property). The script keeps the playhead looping in the current frame until the movie finishes loading into memory.

-- Lingo syntax
on exitFrame
  if member("Intro Movie").percentStreamed < 100 then
    member("Message Line").text = \
    string(member("Intro Movie").bytesStreamed) && "of" && \
    string(member("Intro Movie").streamSize) && "bytes have downloaded so far."
    _movie.go(_movie.frame)
  end if
end

// JavaScript syntax
function exitFrame() {
  var pctStm = member("Intro Movie").percentStreamed;
  var strim = new String(member("Intro Movie").streamSize);
  var strStm = new String(member("Intro Movie").bytesStreamed);
  if (pctStm < 100) {
    member("Message Line").text = strim + " of " + strStm + " bytes have downloaded so far.";
    movie.go(_movie.frame);
  }
}
streamSize (3D)

Usage

member(whichCastmember).streamSize

Description

3D property; allows you to get the size of the data stream to be downloaded, from 0 to maxInteger. This command refers to the initial file import or the last loadFile() requested.

Example

This statement shows that the last file load associated with the cast member Scene has a total size of 325300 bytes:

put member("Scene").streamSize
-- 325300

See also

bytesStreamed (3D), percentStreamed (3D), state (3D), preLoad (3D)

strokeColor

Usage

-- Lingo syntax
memberObjRef.strokeColor

// JavaScript syntax
memberObjRef.strokeColor;

Description

Vector shape cast member property; indicates the color in RGB of the shape’s framing stroke.

To see an example of strokeColor used in a completed movie, see the Vector Shapes movie in the Learning/Lingo Examples folder inside the Director application folder.

Example

This sets the strokeColor of cast member “line” to red:

-- Lingo syntax
member("line").strokeColor = color(255, 0, 0)

// JavaScript syntax
member("line").strokeColor = color(255, 0, 0);

See also

color(), fillColor, endColor, backgroundColor
**strokeWidth**

**Usage**

-- Lingo syntax
memberObjRef.strokeWidth

// JavaScript syntax
memberObjRef.strokeWidth;

**Description**

Vector shape cast member property; indicates the width, in pixels, of the shape's framing stroke. The value is a floating-point number between 0 and 100 and can be tested and set.

To see an example of `strokeWidth` used in a completed movie, see the Vector Shapes movie in the Learning/Lingo Examples folder inside the Director application folder.

**Example**

The following code sets the `strokeWidth` of cast member “line” to 10 pixels:

-- Lingo syntax
member("line").strokeWidth = 10

// JavaScript syntax
member("line").strokeWidth = 10;

**style**

**Usage**

member(whichCastmember).model(whichModel).toon.style

member(whichCastmember).model(whichModel).shader.style

member(whichCastmember).shader(whichShader).style

**Description**

3D toon modifier and painter shader property; indicates the way the toon modifier and painter shader apply color to a model. Possible values are as follows:

- `#toon` uses sharp transitions between colors.
- `#gradient` uses smooth transitions between colors. This is the default value.
- `#blackAndWhite` uses two-color black and white.

The number of colors used by the toon modifier and painter shader is set with the `colorSteps` property of the modifier or shader.

**Example**

The following statement sets the `style` property of the toon modifier for the model named Teapot to `#blackAndWhite`. The model will be rendered in two-color black and white.

member("Shapes").model("Teapot").toon.style = #blackAndWhite
subdivision

Usage

member(\textit{whichCastmember}).model(\textit{whichModel}).sds.subdivision

Description

3D \textit{sds} modifier property; allows you to get or set the subdivision surfaces mode of operation. Possible values are as follows:

- \texttt{#uniform} specifies that the mesh is uniformly scaled up in detail, with each face subdivided the same number of times.
- \texttt{#adaptive} specifies that additional detail is added only when there are large surface orientation changes and only to those areas of the mesh that are currently visible.

The \textit{sds} modifier cannot be used with the \textit{inker} or \textit{toon} modifiers, and caution should be used when using the \textit{sds} modifier with the \textit{lod} modifier. See the \textit{sds} modifier entry for more information.

Example

The following statement sets the subdivision property of the \textit{sds} modifier of the model named Baby to \texttt{#adaptive}. Baby's geometry will not be modified uniformly.

\begin{verbatim}
member(“Scene”).model(“Baby”).sds.subdivision = #adaptive
\end{verbatim}

See also

\textit{sds (modifier)}, \textit{error}, \textit{enabled (sds)}, \textit{depth (3D)}, \textit{tension}

subPicture

Usage

\begin{verbatim}
-- Lingo syntax
dvdObjRef.subPicture

// JavaScript syntax
dvdObjRef.subPicture;
\end{verbatim}

Description

DVD property. Determines the current subpicture, if any. Read/write.

The value of \textit{subPicture} is an integer. A value of 0 disables \textit{subPicture}.

See also

\textit{DVD}

subPictureCount

Usage

\begin{verbatim}
-- Lingo syntax
dvdObjRef.subPictureCount

// JavaScript syntax
dvdObjRef.subPictureCount;
\end{verbatim}

\text{subPictureCount 1011}
Description
DVD property. Returns the number of available sub pictures. Read-only.

See also
DVD
suspendUpdates
Usage
sprite(which3dSprite).suspendUpdates
Description
3D sprite property; when set to TRUE, causes the sprite not to be updated as part of normal screen redraw operations. This can improve movie playback performance. Certain kinds of screen updates will still affect the sprite, such as those due to dragging another window over the sprite. When the suspendUpdates property is set to FALSE, the sprite is redrawn normally.

It is important to keep the suspendUpdates property set to FALSE while any element within the 3D sprite is being animated.

switchColorDepth
Usage
-- Lingo syntax
_player.switchColorDepth
// JavaScript syntax
_player.switchColorDepth;
Description
Player property; determines whether Director switches the monitor that the Stage occupies to the color depth of the movie being loaded (TRUE) or leaves the color depth of the monitor unchanged when a movie is loaded (FALSE, default). Read/write.

When switchColorDepth is TRUE, nothing happens until a new movie is loaded.

Setting the monitor’s color depth to that of the movie is good practice.

• When the monitor’s color depth is set below that of the movie, resetting it to the color depth of the movie (assuming that the monitor can provide that color depth) helps maintain the movie’s original appearance.

• When the monitor’s color depth is higher than that of the movie, reducing the monitor’s color depth plays the movie using the minimum amount of memory, loads cast members more efficiently, and causes animation to occur more quickly.

The value of this property can also be set using the Reset Monitor to Movie’s Color Depth option in the General Preferences dialog box.

Example
This statement sets the variable named switcher to the current setting of switchColorDepth:
-- Lingo syntax
switcher = _player.switchColorDepth
// JavaScript syntax
switcher = _player.switchColorDepth;
// JavaScript syntax
var switcher = _player.switchColorDepth;

This statement checks whether the current color depth is 8-bit and turns the switchColorDepth property on if it is:

-- Lingo syntax
if (_system.colorDepth = 8) then
    _player.switchColorDepth = TRUE
end if

// JavaScript syntax
if (_system.colorDepth == 8) {
    _player.switchColorDepth = true;
}

See also
colorDepth, Player

**systemTrayIcon**

**Usage**

-- Lingo syntax
_movie.displayTemplate.systemTrayIcon
windowObjRef.systemTrayIcon

// JavaScript syntax
_movie.displayTemplate.systemTrayIcon;
windowObjRef.systemTrayIcon;

**Description**

Movie and Windows property (Microsoft Windows only). Determines whether a window has an icon in the system tray of a user's desktop. Read/write.

If systemTrayIcon is TRUE, a window icon is placed in the system tray.

If systemTrayIcon is FALSE, no icon appears in the system tray.

See also
displayTemplate, Movie, systemTrayTooltip, Window

**systemTrayTooltip**

**Usage**

-- Lingo syntax
_movie.displayTemplate.systemTrayTooltip
windowObjRef.systemTrayTooltip

// JavaScript syntax
_movie.displayTemplate.systemTrayTooltip;
windowObjRef.systemTrayTooltip;

**Description**

Movie and Windows property (Microsoft Windows only). Determines the string that appears in the tooltip pop-up of the system tray icon. Read/write.
This property is only applicable if the systemTrayIcon property is set to TRUE. If systemTrayIcon is TRUE, the tooltip will appear when a user mouses over the system tray icon.

The default value of systemTrayTooltip is the title of the window.

See also
displayTemplate, Movie, systemTrayIcon, Window

tabCount

Usage
chunkExpression.tabCount

Description
Text cast member property; indicates how many unique tab stops are in the specified chunk expression of the text cast member.
The value is an integer equal to or greater than 0, and may be tested but not set.

tabs

Usage
member(whichTextMember).tabs

Description
Text cast member property; this property contains a list of all the tab stops set in the text cast member.
Each element of the list contains information regarding that tab for the text cast member. The possible properties in the list are as follows:

<table>
<thead>
<tr>
<th>#type</th>
<th>Can be #left, #center, #right, or #decimal.</th>
</tr>
</thead>
<tbody>
<tr>
<td>#position</td>
<td>Integer value indicating the position of the tab in points.</td>
</tr>
</tbody>
</table>

You can get and set this property. When tabs is set, the type property is optional. If type is not specified, the tab type defaults to #left.

Example

This statement retrieves and displays in the Message window all the tabs for the text cast member Intro credits:

```
put member("Intro credits").tabs
-- [[#type: #left, #position: 36], [#type: #Decimal, #position: 141], 
   [#type: #right, #position: 216]]
```
target

Usage

`timeoutObject.target`

Description

Timeout object property; indicates the child object that the given `timeoutObject` will send its timeout events to. Timeout objects whose target property is `VOID` will send their events to a handler in a movie script.

This property is useful for debugging behaviors and parent scripts that use timeout objects.

Example

This statement displays the name of the child object that will receive timeout events from the timeout object `timerOne` in the Message window:

```
put timeout("timerOne").target
```

See also

`name (timeout), timeout(), timeoutHandler, timeoutList`

targetFrameRate

Usage

`sprite(which3dSprite).targetFrameRate`

Description

3D sprite property; determines the preferred number of frames per second to use when rendering a 3D sprite. The default value is 30 frames per second. The `targetFrameRate` property is only used if the `useTargetFrameRate` property is set to `TRUE`. If the `useTargetFrameRate` property is set to `TRUE`, Director will reduce the polygon count of the models in the sprite if necessary to maintain the specified frame rate.

Example

These statements set the `targetFrameRate` property of sprite 3 to 45 and enforce the frame rate by setting the `useTargetFrameRate` property of the sprite to `TRUE`:

```
sprite(3).targetFrameRate = 45
sprite(3).useTargetFrameRate = TRUE
```

See also

`useTargetFrameRate`
tension

Usage

\[ \text{member}(\text{whichCastmember}).\text{model}(\text{whichModel}).\text{sds.tension} \]

Description

3D subdivision surface property; allows you to get or set a floating-point percentage between 0.0 and 100.0 that controls how tightly the newly generated surface matches the original surface. The higher this value, the more tightly the subdivided surface matches the original surface. The default is 65.0.

Example

The following statement sets the tension property of the sds modifier of the model Baby to 35. If the sds modifier's error setting is low and its depth setting is high, this statement will have a very pronounced effect on Baby's geometry.

\[ \text{member("scene").model("Baby").sds.tension = 35} \]

See also

sds (modifier), error, depth (3D)

text

Usage

-- Lingo syntax
\[ \text{memberObjRef.text} \]

// JavaScript syntax
\[ \text{memberObjRef.text;} \]

Description

Text cast member property; determines the character string in the field cast member specified by whichCastMember.

The text cast member property is useful for displaying messages and recording what the user types.

This property can be tested and set.

When you use Lingo to change the entire text of a cast member you remove any special formatting you have applied to individual words or lines. Altering the text cast member property reapplies global formatting. To change particular portions of the text, refer to lines, words, or items in the text.

When the movie plays back as an applet, this property's value is "" (an empty string) for a field cast member whose text has not yet streamed in.

To see an example of text used in a completed movie, see the Forms and Post, and Text movies in the Learning/Lingo Examples folder inside the Director application folder.
Example

This statement places the phrase “Thank you.” in the empty cast member Response:

--Lingo syntax
if (member("Response").text = EMPTY) then
    member("Response").text = "Thank You."
end if

// JavaScript syntax
if (member("Response").text = " ") {
    member("Response").text = "Thank You.");
}

This statement sets the content of cast member Notice to “You have made the right decision!”

--Lingo syntax
member("Notice").text = "You have made the right decision!"

// JavaScript syntax
member("Notice").text = "You have made the right decision!";

See also
selEnd, selStart

texture

Usage

member(whichCastmember).texture(whichTexture)
member(whichCastmember).texture[index]
member(whichCastmember).shader(whichShader).texture
member(whichCastmember).model(whichModel).shader.texture
member(whichCastmember).model(whichModel).shaderList.texture
member(whichCastmember).model(whichModel).shaderList[index].texture
member(whichCastmember).modelResource(whichParticleSystemModel)\Resource).texture

Description

3D element and shader property; an image object used by a shader to define the appearance of the surface of a model. The image is wrapped onto the geometry of the model by the shader.

The visible component of a shader is created with up to eight layers of textures. These eight texture layers are either created from bitmap cast members or image objects within Director or imported with models from 3D modeling programs.

Create and delete textures with the newTexture() and deleteTexture() commands.

Textures are stored in the texture palette of the 3D cast member. They can be referenced by name (whichTexture) or palette index (textureIndex). A texture can be used by any number of shaders. Changes to a texture will appear in all shaders which use that texture.

There are three types of textures:

#fromCastmember; the texture is created from a bitmap cast member using the newTexture() command.
#fromImageObject; the texture is created from a lingo image object using the newTexture() command.
#importedFromFile; the texture is imported with a model from a 3D modeling program.
For more information about texture properties, see the Using Director topics in the Director Help Panel.

The texture of a particle system is a property of the model resource, whose type is `particle`.

**Example**

This statement sets the *texture* property of the shader named WallSurface to the texture named BluePaint:

```lua
member("Room").shader("WallSurface").texture = \n    member("Room").texture("BluePaint")
```

**See also**

`newTexture`, `deleteTexture`

---

**textureCoordinateList**

**Usage**

```lua
member(whichCastmember).modelResource(whichmodelResource).textureCoordinateList
modelResourceObjectReference.textureCoordinateList
```

**Description**

3D property; when used with a model resource whose type is `mesh`, or with a `meshDeform` modifier attached to a model, this property allows you to get or set the *textureCoordinateList* property of the model resource.

The *textureCoordinateList* property is a list of sublists identifying locations in an image that are to be used when texture mapping a triangle. Each sublist consists of two values indicating a location in a texture map. The values must be between 0.0 and 1.0 so that they can be scaled to arbitrarily sized texture maps. The default is an empty list.

**Manipulate** `modelResource.face[index].textureCoordinates` or `model.meshdeform.mesh[index].face[index]` to change the mapping between `textureCoordinates` and the corners of a mesh face.

**Example**

```lua
put member(5,2).modelResource("mesh square").\n    textureCoordinateList
  --[ [0.1, 0.1], [0.2, 0.1], [0.3, 0.1], [0.1, 0.2], [0.2, 0.2], [0.3, 0.2], [0.1, 0.3], [0.2, 0.3], [0.3, 0.3] ]
```

**See also**

`face`, `texture`, `meshDeform (modifier)`
textureCoordinates

Usage

member(whichCastmember).modelResource(whichModelResource).\n  face[faceIndex].textureCoordinates
modelResourceObject.face[faceIndex].textureCoordinates

Description

3D property; identifies which elements in the textureCoordinateList to use for the faceIndex’d face. This property must be a list of three integers specifying indices in the textureCoordinateList, corresponding to the textureCoordinates to use for each corner of the mesh’s face.

See also

face, textureCoordinateList

textureLayer

Usage

member(whichCastmember).model(whichModel).meshDeform.mesh[index].\n  texturelayer.count
member(whichCastmember).model(whichModel).meshdeform.mesh[index].\n  texturelayer.add()
member(whichCastmember).model(whichModel).meshdeform.mesh[index].\n  texturelayer[index].textureCoordinateList.

Description

3D meshdeform modifier properties; using these properties you can get and set information about the texture layers of a specified mesh.

You can have up to eight texture layers for a shader, each layer can contain only one texture, but the same texture can be specified for more than one layer. Texture layers are layers of textures used by shaders.

Use the following properties to access and manipulate texture layers:

meshdeform.mesh[index].texturelayer.count returns the number of texture layers for the specified mesh.

model.meshdeform.mesh[index].texturelayer.add() adds an empty texture layer to the specified mesh.

model.meshdeform.mesh[index].texturelayer[index].texturecoordinatelist allows you to set or get a list of textureCoordinates for a particular layer of the specified mesh. You can also use this property to copy texture coordinates between texture layers as follows:

model.meshdeform.texturelayer[a].texturecoordinatelist = \n  model.meshdeform.texturelayer[b].texturecoordinatelist

See also

meshDeform (modifier), mesh (property), textureCoordinateList, add (3D texture), count, texture, textureModelist
**textureList**

**Usage**

member(whichMember).model(whichModel).shader(whichShader).textureList

member(whichMember).model(whichModel).shader(whichShader).textureList[index]

**Description**

3D shader property; determines the list of textures applied to the shader. A shader can have up to 8 layers of textures. When tested, this property returns a linear list of texture objects. When set without specifying an index, this property specifies the texture object to be applied to all layers. Setting the `textureList` property to VOID disables texturing for all layers. The default value is VOID.

To test or set the texture object for a specific texture layer, include an index value.

**Example**

This statement sets the 3rd texture layer of the shader named “WallSurface” to the texture named “BluePaint” in the cast member named “Room”:

```
member(3).model("Car").shader("WallSurface").textureList[3] = \n  member("Room").texture("BluePaint")
```

**See also**

`textureModeList`

**textureMember**

**Usage**

member(whichCastmember).textureMember

**Description**

3D cast member property; indicates the name of the bitmap cast member used as the source of the default texture for the 3D cast member.

The 3D cast member’s `textureType` property must be set to #member for the `textureMember` property to be effective.

**Example**

The following statement sets the `textureMember` property of the cast member named YardScene to "Fence". If the `textureType` property of YardScene is set to #member, the cast member named Fence will be the source bitmap for the default texture in YardScene.

```
member("YardScene").textureMember = "Fence"
```

**See also**

`textureType`
textureMode

Usage
member(whichCastmember).shader(whichShader).textureMode
member(whichCastmember).model(whichModel).shader.textureMode
member(whichCastmember).model(whichModel).shaderList[[index]].
  textureMode

Description
3D #standard shader property; specifies how the first texture layer is mapped onto the surface of
the model. Use the textureModeList property to specify textures for layers other than the first
layer. This property is ignored if the #toon modifier is applied to the model resource.

The possible values of this property are #none, #wrapPlanar, #wrapCylindrical,
#wrapSpherical, #reflection, #diffuseLight, and #specularLight. For descriptions of
these terms, see textureModeList.

Example
This statement sets the value of the textureMode property of the first texture layer of the shader
of the model named Ball to #wrapSpherical:
member("scene").model("Ball").shader.textureMode = #wrapSpherical

See also
  textureModeList

textureModeList

Usage
member(whichCastmember).shader(whichShader).textureModeList
member(whichCastmember).shader(whichShader).
  textureModeList[textureLayerIndex]
member(whichCastmember).model(whichModel).shader.textureModeList
member(whichCastmember).model(whichModel).shader.
  textureModeList[textureLayerIndex]

Description
3D standard shader property; allows you to change how a textureLayer is mapped onto
the surface of a model. This property is ignored if the #toon modifier is applied to the model
resource. Possible values are as follows:

• #none uses the texture coordinate values originally defined for the model resource. This setting
disables wrapTransform and wrapTransformList[textureLayerIndex].
• #wrapPlanar wraps the texture on the model surface as though it were being projected from
  an overhead projector. The shader's wrapTransformList[textureLayerIndex] is applied to
  the mapping space before the texture coordinates are generated in model space. With an
  identity wrapTransformList[textureLayerIndex] (the default), the planar mapping is
  oriented such that the texture is extruded along the Z axis with the texture's up direction along
  the Y axis.
**#wrapCylindrical** wraps the texture around the surface as though the surface were placed in the middle of the texture and then the texture were rolled around the surface to form a cylinder. The \texttt{wrapTransformList[textureLayerIndex]} is applied to the mapping space before the texture coordinates are generated in model space. With an identity \texttt{wrapTransformList[textureLayerIndex]} (the default), the cylindrical mapping is oriented such that the texture is wrapped from the -Y axis, starting at the left edge of the texture, toward the +X axis, around the Z axis. The up direction of the texture is toward the +Z axis.

**#wrapSpherical** wraps the texture around the surface as though the surface were placed in the middle of the texture and then all four corners of the texture were pulled up to meet at the top. The \texttt{wrapTransformList[textureLayerIndex]} is applied to the mapping space before the texture coordinates are generated in model space. With an identity \texttt{wrapTransformList[textureLayerIndex]}, the spherical mapping is located at the model space origin and oriented such that the texture is wrapped from the -Y axis, starting at the left edge of the texture, toward the +X axis, around the Z axis. The up direction of the texture is toward the +Z axis.

**#reflection** is similar to **#wrapSpherical** except that the new texture coordinates are continuously reprojected onto the surface from a fixed orientation. When the model rotates, the texture coordinates will not rotate with it. Simulates light reflected on an object by its environment. This setting disables \texttt{wrapTransform}.

**#diffuseLight** generates diffuse light mapping texture coordinate values, one per vertex, and stores the results in the referenced mesh. This setting disables \texttt{wrapTransform}.

**#specularLight** generates specular light mapping texture coordinate values, one per vertex, and stores the results in the referenced mesh. This setting disables \texttt{wrapTransform}.

### Example

In this example, a shader is set up to simulate a reflective garden ball. The shader’s first textureLayer is set to a spherical mapping and the third textureLayer is set to use a **reflection** style mapping. The shader’s textureList[3] entry will appear to reflected from the environment onto all models which use this shader.

```plaintext
member("scene").shader("GardenBall").textureList[1] = 
    member("scene").texture("FlatShinyBall")
member("scene").shader("GardenBall").textureModeList[1] = "
    #wrapSpherical"
member("scene").shader("GardenBall").textureList[3] = 
    member("scene").texture("GardenEnvironment")
member("scene").shader("GardenBall").textureModeList[3] = "
    #reflection"
```

### See also

\texttt{textureTransformList, wrapTransform}
textureRenderFormat

Usage
getRendererServices().textureRenderFormat

Description
3D rendererServices property; allows you to get or set the default bit format used by all textures in all 3D cast members. Use a texture's texture.RenderFormat property to override this setting for specific textures only. Smaller sized bit formats (i.e., 16-bit variants such as #rgba5551) use less hardware accelerator video ram, allowing you to make use of more textures before being forced to switch to software rendering. Larger sized bit formats (i.e., 32-bit variants such as #rgba8888) generally look better. In order to use alpha transparency in a texture, the last bit must be nonzero. In order to get smooth transparency gradations, the alpha channel must have more than 1 bit of precision.

Each pixel format has four digits, with each digit indicating the degree of precision for red, green, blue, and alpha. The value you choose determines the accuracy of the color fidelity (precision of the alpha channel) and the amount of memory used by the hardware texture buffer. You can choose a value that improves color fidelity or a value that allows you to fit more textures on the card. You can fit twice as many 16-bit textures as 32-bit textures in the same space. If a movie uses more textures than fit on a card at a time, Director switches to #software rendering.

You can specify any of the following values for textureRenderFormat:
- #rgba8888: 32-bit color mode with 8 bits each for red, green, blue, and alpha
- #rgba8880: same as above, with no alpha value
- #rgba5650: 16-bit color mode with no alpha; 5 bits for red, 6 for green, 5 for blue
- #rgba5550: 16-bit color mode with no alpha; 5 bits each for red, green, and blue, with no alpha measure
- #rgba5551: 16-bit color mode with 5 bits each for red, green, and blue; 1 bit for alpha
- #rgba4444: 16-bit color mode with 4 bits each for red, green, blue, and alpha

The default value is #rgba5551.

Example
The following statement sets the global textureRenderFormat for the 3D member to #rgba8888. Each texture in this movie will be rendered in 32-bit color unless its texture.renderFormat property is set to a value other than #default.
getRendererServices().textureRenderFormat = #rgba8888

See also
renderer, preferred3dRenderer, renderFormat, getRendererServices()
**textureRepeat**

**Usage**

```plaintext
member(whichCastmember).shader(whichShader).textureRepeat
member(whichCastmember).model(whichModel).shader.textureRepeat
member(whichCastmember).model(whichModel).shaderList[[index]].
  textureRepeat
```

**Description**

3D `#standard` shader property; controls the texture clamping behavior of the first texture layer of the shader. Use the `textureRepeatList` property to control this property for texture layers other than the first layer.

When `textureRepeat` is set to `TRUE` and the value of the x and/or y components of `shaderReference.textureTransform.scale` is less than 1, the texture is tiled (repeated) across the surface of the model.

When `textureRepeat` is set to `FALSE`, the texture will not tile. If the value of the x and/or y components of `shaderReference.textureTransform.scale` is less than 1, any area of the model not covered by the texture will be black. If the value of the x and/or y components of `shaderReference.textureTransform.scale` is greater than 1, the texture is cropped as it extends past the texture coordinate range.

The default value of this property is `TRUE`. This property is always `TRUE` when using the `#software` renderer.

**Example**

The following statement sets the `textureRepeat` property of the first shader used by the model named `gbCyl3` to `TRUE`. The first texture in that shader will tile if the value of the x or y component of its `textureTransform` or `textureTransformList` property is less than 1.

```plaintext
member("scene").model("gbCyl3").shader.textureRepeat = TRUE
```

**See also**

`textureTransform, textureTransformList`

**textureRepeatList**

**Usage**

```plaintext
shaderReference.textureRepeatList[textureLayerIndex]
member(whichCastmember).shader(whichShader).textureRepeatList[textureLayerIndex]
member(whichCastmember).shader[shaderListIndex].textureRepeatList[textureLayerIndex]
member(whichCastmember).model(whichModel).shader.textureRepeatList[textureLayerIndex]
member(whichCastmember).model(whichModel).shaderList[shaderListIndex].textureRepeatList[textureLayerIndex]
```
Description

3D standard shader property; allows you to get or set the texture clamping behavior of any texture layer. When "TRUE", the default, the texture in textureLayerIndex can be tiled (repeated) several times across model surfaces. This can be accomplished by setting shaderReference.textureTransform[textureLayerIndex].scale to be less than 1 in x or y. When this value is set to "FALSE", the texture will apply to a smaller portion of model surfaces, rather than tile across those surfaces, when the shaderReference.textureTransform[textureLayerIndex].scale is less than 1 in x or y. Think of it as shrinking the source image within the frame of the original image and filling in black around the gap. Similarly, if shaderReference.textureTransform[textureLayerIndex].scale is set to be greater than 1 in x or y, the image will be cropped as the border of the texture is extended past the texture coordinate range.

Example

The following code will textureMap a sphere entirely with a granite texture repeated 4 times across the surface, and a logo image which covers just 1/4 of the surface.

```plaintext
m = member(2).model("mySphere")
f = member(2).newTexture("granite", #fromCastmember, 
   member("granite"))
g = member(2).newTexture("logo", #fromCastmember, member("logo"))
s = member(2).newShader("s", #standard)
s.textureList[1] = g
s.textureRepeatList[2] = false
s.textureTransformList[1].scale(0.5,0.5,1.0)
s.textureTransformList[2].scale(0.5,0.5,1.0)
s.textureModelList[2] = #wrapPlanar
s.blendFunctionList[2] = #add
m.shaderList = s
```

textureTransform

Usage

member(whichCastmember).shader(whichShader).textureTransform
member(whichCastmember).model(whichModel).shader.textureTransform
member(whichCastmember).model(whichModel).shaderList[[index]].
   textureTransform

Description

3D #standard shader property; provides access to a transform which modifies the texture coordinate mapping of the first texture layer of the shader. Manipulate this transform to tile, rotate, or translate the texture before applying it to the surface of the model. The texture itself remains unaffected; the transform merely modifies how the shader applies the texture. The textureTransform property is applied to all texture coordinates regardless of the textureMode property setting. This is the last modification of the texture coordinates before they are sent to the renderer. The textureTransform property is a matrix that operates on the texture in TextureImage space. TextureImage space is defined to exist only on the X,Y plane.
To tile the image twice along its horizontal axis, use
shaderReference.textureTransform.scale(0.5, 1.0, 1.0). Scaling on the Z axis
is ignored.

To offset the image by point(xOffset, yOffset), use
shaderReference.textureTransform.translate(xOffset, yOffset, 0.0). Translating by
ints when the shader's textureRepeat property is TRUE will have no effect, because the width
and height of the texture will be valued between 0.0 and 1.0 in that case.

To apply a rotation to a texture layer, use
shaderReference.textureTransform.rotate(0, 0, angle). Rotations around the Z axis are
rotated around the (0, 0) 2d image point, which maps to the upper left corner of the texture.
Rotations about the X and Y axes are ignored.

Just as with a model’s transform, textureTransform modifications are layerable. To rotate the
texture about a point(xOffset, yOffset) instead of point(0,0), first translate to point(0 - xOffset,
0 - yOffset), then rotate, then translate to point(xOffset, yOffset). The textureTransform is
similar to the shader’s wrapTransform property with the following exceptions. It is applied in 2d
image space rather than 3d world space. As a result, only rotations about the Z axis and
translations and scales on X and Y axes are effective. The transform is applied regardless of the
shaderReference.textureMode setting. The wrapTransform, by comparison, is only effective
when the textureMode is #wrapPlanar, #wrapCylindrical, or #wrapSpherical.

**Example**

This statement shows the textureTransform of the first texture in the first shader used by the
model gbCyl3:

```plaintext
put member("Scene").model("gbCyl3").shader.textureTransform
-- transform(1.0000, 0.0000, 0.0000, 0.0000, 0.0000, 1.0000, \
 0.0000, 0.0000, 0.0000, 1.0000, 0.0000, 0.0000, 0.0000, 0.0000, 0.0000, \
0.0000, 1.0000)
```

The following statement halves the height and width of the first texture used by the shader named
gbCyl3. If the textureRepeat property of gbCyl3 is set to TRUE, four copies of the texture will be	
tiled across the shader.

```plaintext
member("Scene").shader("gbCyl3").textureTransform.scale = \vector(0.5, 0.5, 1)
```

This statement rotates the first texture used by the shader gbCyl3 by 90° from vector(0, 0, 0):

```plaintext
member("Scene").shader("gbCyl3").textureTransform.rotation = \vector(0, 0, 90)
```

**textureTransformList**

**Usage**

```plaintext
shaderReference.textureTransformList[textureLayerIndex]
member(whichCastmember).shader(ShaderName).textureTransformList[\textureLayerIndex]
member(whichCastmember).shader[shaderListIndex].texture\TransformList[textureLayerIndex]
member(whichCastmember).model(modelName).shader\TransformList[textureLayerIndex]
member(whichCastmember).model(modelName).shaderList[\shaderListIndex].textureTransformList[textureLayerIndex]
```
Description
3D standard shader property; this property provides access to a transform which modifies the
texture coordinate mapping of a texture layer. Manipulate this transform to tile, rotate, or
translate a texture image before applying it to the surface of models. The texture itself remains
unaffected, the transform merely modifies how the shader applies the texture.

To tile the image twice along its horizontal axis, use
```
textureTransformList[whichTextureLayer].scale(0.5, 1.0, 1.0).
```
Scales in Z will be ignored since images are 2D in nature. Care must be taken to avoid 0.0 scales (even in Z), as that
will negate the effect of the entire texture.

To offset the image by point(xOffset,yOffset), use
```
textureTransformList[whichTextureLayer].translate(xOffset,yOffset,0.0).
```
Translating by integers when that texture layer's textureRepeat property is TRUE will have no
effect, because the width and height of the texture will be valued between 0.0 and 1.0 in that case.

To apply a rotation to a texture layer, use
```
textureTransformList[whichTextureLayer].rotate(0,0,angle).
```
Rotations around the Z axis are rotated around the (0,0) 2D image point, which maps to the upper left corner of the
texture. Rotations about X and Y will be ignored since images are 2D by nature.

Just as with a model's transform, textureTransform modifications are layerable. To rotate the
image about a point(xOffset,yOffset) instead of point(0,0), first translate to point(0 - xOffset,
0 - yOffset), then rotate, then translate to point(xOffset, yOffset).

The textureTransformList is similar to the shader wrapTransformList property with the
following exceptions.

It is applied in 2D image space rather than 3D world space. As a result, only rotations in Z, and
translations and scales in X and Y, are effective.

The transform is applied regardless of the shaderReference.textureModeList[index] setting.
The wrapTransform, by comparison, is only effective when the textureMode is #wrapPlanar,
#wrapCylindrical, or #wrapSpherical.

Example
This statement shows the textureTransform of the third texture in the first shader used by the
model gbCyl3:
```
put member("scene").model("gbCyl3").shader.textureTransformList[3] =
    transform(1.0000, 0.0000, 0.0000, 0.0000, 0.0000, 1.0000, \
    0.0000, 0.0000, 0.0000, 0.0000, 1.0000, 0.0000, \
    0.0000, 1.0000)
```

The following statement halves the height and width of the fifth texture used by the shader
gbCyl3. If the textureRepeatList[5] value of gbCyl3 is set to TRUE, four copies of the texture
will be tiled across the shader.
```
member("scene").shader("gbCyl3").textureTransformList[5].scale = \vector(0.5, 0.5, 1)
```

This statement rotates the fourth texture used by the shader gbCyl3 by 90° from vector(0, 0, 0):
```
member("scene").shader("gbCyl3").textureTransformList[4].rotation = \vector(0, 0, 90)
```
These statements rotate the third texture used by the shader gbCyl3 by 90× around its center, assuming that textureList[3] is a 128x128 sized texture:

```lingo
s = member("scene").shader("gbCyl3")
s.textureTransformList[3].translate(-64,-64,0)
s.textureTransformList[3].rotate(0,0,90)
s.textureTransformList[3].translate(64,64,0)
```

**textureType**

**Usage**

```lingo
member(whichCastmember).textureType
```

**Description**

3D texture property; allows you to get or set the texture type for the default texture. Possible values are as follows:

- `#none` specifies that there is no texture type.
- `#default` uses the texture from the original shader as the texture.
- `#member` uses the image from the specified cast member as the texture.

The default value for this property is `#default`. You must specify `#member` for this property in order to use the `textureMember` property.

**Example**

The following statement sets the `textureType` property of the cast member Scene to `#member`.

```lingo
member("Scene").textureType = #member
```

This makes it possible to use a bitmap cast member as the source of the default texture by setting the `textureMember` property. The bitmap cast member is named “grass”.

```lingo
member("Scene").textureMember = "grass"
```

**See also**

- `textureMember`

**thumbNail**

**Usage**

- **Lingo syntax**
  ```lingo
  memberObjRef.thumbNail
  ```

- **JavaScript syntax**
  ```javascript
  memberObjRef.thumbNail;
  ```

**Description**

Member property; contains the image used to preview a cast member in the Cast window. Read/write during authoring only.

The image can be customized for any cast member.
Example

The following statement shows how to use a placeholder cast member to display another thumbnail on the Stage. The placeholder cast member is placed on the Stage, then the picture of that member is set to the thumbnail of member 10. This makes it possible to show a reduced image without having to scale or otherwise manipulate a graphic:

-- Lingo syntax
member("Placeholder").picture = member(10).thumbNail

// JavaScript syntax
member("Placeholder").picture = member(10).thumbNail;

See also
Member

tilt

Usage

-- Lingo syntax
spriteObjRef.tilt

// JavaScript syntax
spriteObjRef.tilt;

Description

QuickTime VR sprite property; the current tilt, in degrees, of the QuickTime VR movie. This property can be tested and set.

time (timeout object)

Usage

timeoutObject.time

Description

Timeout object property; the system time, in milliseconds, when the next timeout event will be sent by the given timeoutObject. This is not the time until the next event, but the absolute time of the next timeout event.

Example

This handler determines the time remaining until the next timeout event will be sent by the timeout object Update by calculating the difference between its time property and the current value of the milliseconds and displaying the result in the field Time Until:

on prepareFrame
  msBeforeUpdate = timeout("Update").time - the milliseconds
  secondsBeforeUpdate = msBeforeUpdate / 1000
  minutesBeforeUpdate = secondsBeforeUpdate / 60
  member("Time Until").text = string(minutesBeforeUpdate) "minutes before next timeout" end
timeoutHandler

Usage

`timeoutObject.timeoutHandler`

Description

System property; represents the name of the handler that will receive timeout messages from the given `timeoutObject`. Its value is a symbol, such as `#timeExpiredHandler`. The `timeoutHandler` is always a handler within the timeout object's `target` object, or in a movie script if the timeout object has no `target` specified.

This property can be tested and set.

Example

This statement displays the `timeoutHandler` of the timeout object Quiz Timer in the Message window:

```
put timeout("Quiz Timer").timeoutHandler
```

See also

target, timeout(), timeoutList

timeoutList

Usage

```
// Lingo syntax
_movie.timeoutList

// JavaScript syntax
_movie.timeoutList;
```

Description

Movie property; a linear list containing all currently active timeout objects. Read-only.

Use the `forget()` method to delete a timeout object.

Timeout objects are added to the `timeoutList` with the `new()` method.

Example

This statement deletes the third timeout object from the timeout list:

```
// Lingo syntax
_movie.timeoutList[3].forget()

// JavaScript syntax
_movie.timeoutList[3].forget();
```

See also

`forget()` (Window), Movie, `new()`
**timeScale**

*Usage*

```plaintext
member(whichCastMember).timeScale
the timeScale of member whichCastMember
```

*Description*

Cast member property; returns the time unit per second on which the digital video's frames are based. For example, a time unit in a QuickTime digital video is 1/600 of a second.

This property can be tested but not set.

*See also*

digitalVideoTimeScale

**title (DVD)**

*Usage*

```plaintext
-- Lingo syntax
dvdObjRef.title

// JavaScript syntax
dvdObjRef.title;
```

*Description*

DVD property; specifies the current title. Read/write.

This property returns an integer that specifies the number of the current title.

*Example*

This statements returns the current title:

```plaintext
-- Lingo syntax
trace (member(1).title) -- 1

// JavaScript syntax
trace (member(1).title); // 1
```

*See also*

dVD

**title (Window)**

*Usage*

```plaintext
-- Lingo syntax
windowObjRef.title

// JavaScript syntax
windowObjRef.title;
```

*Description*

Window property; assigns a title to a window. Read/write.
Example

This statement assigns the title Planets to the fifth window:

-- Lingo syntax
_player.windowList[5].title = "Planets"

// JavaScript syntax
_player.windowList[5].title = "Planets";

See also

Window

titlebarOptions

Usage

-- Lingo syntax
windowObjRef.titlebarOptions

// JavaScript syntax
windowObjRef.titlebarOptions;

Description

Window property; specifies a list of properties that stores the title bar options of a window. Read/write.

The property list contains the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#icon</td>
<td>Specifies the cast member icon to use in the title bar. This property is only available if the title bar is visible (the #visible property is set to TRUE).</td>
</tr>
<tr>
<td>#visible</td>
<td>Specifies whether the title bar is visible. If FALSE, the title bar is not visible, and all other title bar and window properties are unaffected. If TRUE, the title bar is visible, and the window maintains the states of all other title bar and window properties. The default value is TRUE.</td>
</tr>
<tr>
<td>#closebox</td>
<td>Specifies whether a close box appears in the upper right corner of the window. If TRUE, a close box appears. If FALSE, a close box does not appear. The default value is TRUE.</td>
</tr>
<tr>
<td>#minimizebox</td>
<td>Specifies whether a minimize box appears in the upper right corner of the window. If TRUE, a minimize box appears. If FALSE, a minimize box does not appear. The default value is TRUE.</td>
</tr>
<tr>
<td>#maximizebox</td>
<td>Specifies whether a maximize box appears in the upper right corner of the window. If TRUE, a maximize box appears. If FALSE, a maximize box does not appear. The default value is TRUE.</td>
</tr>
<tr>
<td>#sideTitlebar</td>
<td>(Macintosh only) Specifies whether the title bar should appear on the side of the window. If TRUE, the title bar appears on the side of the window. If FALSE, the title bar does not appear on the side of the window. The default value is FALSE.</td>
</tr>
</tbody>
</table>

These properties can also be accessed by using the Movie object's displayTemplate property.
Example
This statement displays in the Message window the available titlebar options for the window named Elements:

-- Lingo syntax
trace(window("Elements").titlebarOptions)

// JavaScript syntax
trace(window("Elements").titlebarOptions);

These statements set the icon property to the bitmap cast member named smallIcon:

-- Lingo syntax
window("Elements").titlebarOptions.icon = member("smallIcon")

// JavaScript syntax
window("Elements").titlebarOptions.icon = member("smallIcon");

See also
appearanceOptions, displayTemplate, Window

titleCount

Usage

-- Lingo syntax
dvdObjRef.titleCount

// JavaScript syntax
dvdObjRef.titleCount;

Description
DVD property; returns the number of available titles. Read-only.
The number of available titles ranges from 1 to 99.

See also
DVD
toolXtraList

Usage

-- Lingo syntax
_player.toolXtraList

// JavaScript syntax
_player.toolXtraList;

Description
Player property; returns a linear list of all tool Xtra extensions available to the Director player. Read-only.

Example
This statement displays in the Message window all available tool Xtra extensions.

-- Lingo syntax
put(_player.toolXtraList)
// JavaScript syntax
put(_player.toolXtraList);

See also
mediaXtraList, Player, scriptingXtraList, transitionXtraList, xtraList
(ExPlayer)

toon (modifier)

Usage
member(whichCastmember).model(whichModel).toon.toonModifierProperty

Description
3D modifier; once you have added the #toon modifier to a model you can get and set the #toon
modifier properties.

The toon modifier draws a model using only a handful of colors, and resulting in a cartoon style
of rendering of the model’s surface. When the #toon modifier is applied, the model’s shader
texture, reflectionMap, diffuseLightMap, specularLightMap, and glossMap properties
are ignored.

When the #toon modifier is used in conjunction with the #inker modifier, the rendered effect is
cumulative and varies depending on which modifier was first applied. The list of modifiers
returned by the modifier property will list #inker or #toon (whichever was added first), but not
both. The toon modifier can not be used in conjunction with the #sds modifier.

The #toon modifier has the following properties:

Note: For more detailed information about the following properties see the individual property
entries.

- style allows you to get or set the style applied to color transitions. The following are the
  possible values:
  #toon gives sharp transitions between available colors.
  #gradient gives smooth transitions between available colors.
  #blackAndWhite gives sharp transition between black and white.
- colorSteps allows you to get or set the number of different colors used for lighting
calculations. When setting this value it is rounded down to nearest power of 2. Allowed values
  are 2, 4, 8, and 16. The default is 2.
- shadowPercentage allows you to get or set the percentage of the colors (colorSteps) defined
  for lighting used to render the shadowed portion of the model’s surface. Possible values range
  from 0 to 100. The default is 50.
- shadowStrength allows you to get or set the level of darkness applied to the shadowed portion
  of the model’s surface. Possible values are any non-negative floating-point number. The default
  value is 1.0.
- highlightPercentage allows you to get or set the percentage of the colors defined for
  lighting (colorSteps) used to render the highlighted portion of the model’s surface. Possible
  values range from 0 to 100. The default is 50.
- highlightStrength allows you to get or set the level of brightness applied to the highlighted
  portion of the model’s surface. Possible values are any non-negative floating-point number.
  The default value is 1.0.
• **lineColor** allows you to get or set the color of lines drawn by the inker. Possible values are any valid Lingo color object. The default value is rgb (0, 0, 0), which is black.

• **creases** allows you to get or set whether lines are drawn in creases. This is a Boolean value; the default value is True.

• **creaseAngle**, if **creases** is set to **TRUE**, allows you to get or set how sensitive the line drawing function of the toon modifier is to the presence of creases.

• **boundary** allows you to get or set whether lines are drawn around the boundary of the surface. This is a Boolean value; the default value is True.

• **lineOffset** allows you to get or set where lines are drawn relative to the shaded surface and the camera. Negative lines move lines toward the camera. Positive values move lines away from the camera. Possible values are floating-point numbers from -100.0 to 100.0. The default value is -2.0.

• **useLineOffset** allows you to get or set whether **lineOffset** is on or off. This is a Boolean value; the default value is False.

• **silhouettes** allows you to get or set whether lines are drawn to define the edges along the border of a model, outlining its shape. This is a Boolean value; the default value is True.

**See also**
addModifier, modifiers, sds (modifier), inker (modifier)

**top**

**Usage**

-- Lingo syntax
spriteObjRef.top

// JavaScript syntax
spriteObjRef.top;

**Description**

Sprite property; returns or sets the top vertical coordinate of the bounding rectangle of a sprite as the number of pixels from the upper left corner of the Stage. Read/write.

**Example**

This statement checks whether the top of sprite 3 is above the top of the Stage and calls the handler **offTopEdge** if it is:

-- Lingo syntax
if (sprite(3).top < 0) then
   offTopEdge() 
end if

// JavaScript syntax
if (sprite(3).top < 0) {
   offTopEdge();
}

**See also**
bottom, height, left, locH, locV, right, Sprite, width
topSpacing

Usage

chunkExpression.topSpacing

Description

Text cast member property; allows you to specify additional spacing applied to the top of each paragraph in the chunkExpression portion of the text cast member.

The value itself is an integer, with less than 0 indicating less spacing between paragraphs and greater than 0 indicating more spacing between paragraphs.

The default value is 0, which results in default spacing between paragraphs.

Example

This statement sets the topSpacing of the second paragraph in text cast member "myText" to 20:

member(1).paragraph[2].topSpacing = 20

See also

bottomSpacing

traceLoad

Usage

-- Lingo syntax
_movie.traceLoad

// JavaScript syntax
_movie.traceLoad;

Description

Movie property; specifies the amount of information that is displayed about cast members as they load. Read/write.

Valid values for traceLoad are as follows.

• 0—Displays no information (default).
• 1—Displays cast members' names.
• 2—Displays cast members' names, the number of the current frame, the movie name, and the file seek offset (the relative amount the drive had to move to load the media).

Example

This statement causes the movie to display the names of cast members as they are loaded:

-- Lingo syntax
_movie.traceLoad = 1

// JavaScript syntax
_movie.traceLoad = 1;

See also

Movie
traceLogFile

Usage

-- Lingo syntax
_movie.traceLogFile

// JavaScript syntax
_movie.traceLogFile;

Description

Movie property; specifies the name of the file in which the Message window display is written. Read/write.

You can close the file by setting the traceLogFile property to EMPTY (Lingo) or an empty string " " (JavaScript syntax). Any output that would appear in the Message window is written into this file. You can use this property for debugging when running a movie in a projector and when authoring.

Example

This statement instructs Lingo to write the contents of the Message window in the file “Messages.txt” in the same folder as the current movie:

-- Lingo syntax
_movie.traceLogFile = _movie.path & "Messages.txt"

// JavaScript syntax
_movie.traceLogFile = _movie.path + "Messages.txt";

This statement closes the file that the Message window display is being written to:

-- Lingo syntax
_movie.traceLogFile = ""

// JavaScript syntax
_movie.traceLogFile = "";

See also

Movie

traceScript

Usage

-- Lingo syntax
_movie.traceScript

// JavaScript syntax
_movie.traceScript;

Description

Movie property; specifies whether the movie’s trace function is on (TRUE) or off (FALSE). Read/write.

When traceScript is on, the Message window displays each line of script that is being executed.

Example

This statement turns the traceScript property on.
See also
Movie

trackCount (Member)

Usage

-- Lingo syntax
memberObjRef.trackCount()

// JavaScript syntax
memberObjRef.trackCount();

Description
Digital video cast member property; returns the number of tracks in the specified digital video cast member.
This property can be tested but not set.

Example
This statement determines the number of tracks in the digital video cast member Jazz Chronicle and displays the result in the Message window:

-- Lingo syntax
put(member("Jazz Chronicle").trackCount())

// JavaScript syntax
trace(member("Jazz Chronicle").trackCount());

trackCount (Sprite)

Usage

-- Lingo syntax
spriteObjRef.trackCount()

// JavaScript syntax
spriteObjRef.trackCount();

Description
Digital video sprite property; returns the number of tracks in the specified digital video sprite.
This property can be tested but not set.

Example
This statement determines the number of tracks in the digital video sprite assigned to channel 10 and displays the result in the Message window:

-- Lingo syntax
put(sprite(10).trackCount())
// JavaScript syntax
trace(sprite(10).trackCount());

**trackEnabled**

**Usage**

```
-- Lingo syntax
spriteObjRef.trackEnabled(whichTrack)

// JavaScript syntax
spriteObjRef.trackEnabled(whichTrack);
```

**Description**

Digital video sprite property; indicates the status of the specified track of a digital video. This property is **TRUE** if the track is enabled and playing. This property is **FALSE** if the track is disabled and no longer playing or is not updating.

This property cannot be set. Use the **setTrackEnabled** property instead.

**Example**

This statement checks whether track 2 of digital video sprite 1 is enabled:

```
-- Lingo syntax
put(sprite(1).trackEnabled(2))

// JavaScript syntax
put(sprite(1).trackEnabled(2));
```

**See also**

**setTrackEnabled()**

**trackNextKeyTime**

**Usage**

```
-- Lingo syntax
spriteObjRef.trackNextKeyTime(whichTrack)

// JavaScript syntax
spriteObjRef.trackNextKeyTime(whichTrack);
```

**Description**

Digital video sprite property; indicates the time of the keyframe that follows the current time in the specified digital video track.

This property can be tested but not set.

**Example**

This statement determines the time of the keyframe that follows the current time in track 5 of the digital video assigned to sprite channel 15 and displays the result in the Message window:

```
-- Lingo syntax
put(sprite(15).trackNextKeyTime(5))

// JavaScript syntax
put(sprite(15).trackNextKeyTime(5));
```
trackNextSampleTime

Usage

-- Lingo syntax
spriteObjRef.trackNextSampleTime(whichTrack)

// JavaScript syntax
spriteObjRef.trackNextSampleTime(whichTrack);

Description

Digital video sprite property; indicates the time of the next sample that follows the digital video’s current time. This property is useful for locating text tracks in a digital video.

This property can be tested but not set.

Example

This statement determines the time of the next sample that follows the current time in track 5 of the digital video assigned to sprite 15:

-- Lingo syntax
put(sprite(15).trackNextSampleTime(5))

// JavaScript syntax
put(sprite(15).trackNextSampleTime(5));

trackPreviousKeyTime

Usage

-- Lingo syntax
spriteObjRef.trackPreviousKeyTime(whichTrack)

// JavaScript syntax
spriteObjRef.trackPreviousKeyTime(whichTrack);

Description

Digital video sprite property; reports the time of the keyframe that precedes the current time. This property can be tested but not set.

Example

This statement determines the time of the keyframe in track 5 that precedes the current time in the digital video sprite assigned to channel 15 and displays the result in the Message window:

-- Lingo syntax
put(sprite(15).trackPreviousKeyTime(5))

// JavaScript syntax
put(sprite(15).trackPreviousKeyTime(5));
trackPreviousSampleTime

Usage

-- Lingo syntax
spriteObjRef.trackPreviousSampleTime(whichTrack)

// JavaScript syntax
spriteObjRef.trackPreviousSampleTime(whichTrack);

Description

Digital video sprite property; indicates the time of the sample preceding the digital video’s current time. This property is useful for locating text tracks in a digital video.

This property can be tested but not set.

Example

This statement determines the time of the sample in track 5 that precedes the current time in the digital video sprite assigned to channel 15 and displays the result in the Message window:

-- Lingo syntax
put(sprite(15).trackPreviousSampleTime(5))

// JavaScript syntax
put(sprite(15).trackPreviousSampleTime(5));

trackStartTime (Member)

Usage

-- Lingo syntax
memberObjRef.trackStartTime(whichTrack)

// JavaScript syntax
memberObjRef.trackStartTime(whichTrack);

Description

Digital video cast member property; returns the start time of the specified track of the specified digital video cast member.

This property can be tested but not set.

Example

This statement determines the start time of track 5 in the digital video cast member Jazz Chronicle and displays the result in the Message window:

-- Lingo syntax
put(member("Jazz Chronicle").trackStartTime(5))

// JavaScript syntax
put(member("Jazz Chronicle").trackStartTime(5));
trackStartTime (Sprite)

Usage

--- Lingo syntax
spriteObjRef.trackStartTime(whichTrack)

// JavaScript syntax
spriteObjRef.trackStartTime(whichTrack);

Description

Digital video sprite property; sets the starting time of a digital video movie in the specified sprite channel. The value of trackStartTime is measured in ticks.

This property can be tested but not set.

Example

In the Message window, the following statement reports when track 5 in sprite channel 10 starts playing. The starting time is 120 ticks (2 seconds) into the track.

--- Lingo syntax
put(sprite(10).trackStartTime(5))

// JavaScript syntax
put(sprite(10).trackStartTime(5));

See also

duration (Member), playRate (QuickTime, AVI), currentTime (QuickTime, AVI)

trackStopTime (Member)

Usage

--- Lingo syntax
memberObjRef.trackStopTime(whichTrack)

// JavaScript syntax
memberObjRef.trackStopTime(whichTrack);

Description

Digital video cast member property; returns the stop time of the specified track of the specified digital video cast member. It can be tested but not set.

Example

This statement determines the stop time of track 5 in the digital video cast member Jazz Chronicle and displays the result in the Message window:

--- Lingo syntax
put(member("Jazz Chronicle").trackStopTime(5))

// JavaScript syntax
put(member("Jazz Chronicle").trackStopTime(5));
trackStopTime (Sprite)

Usage

-- Lingo syntax
spriteObjRef.trackStopTime(whichTrack)

// JavaScript syntax
spriteObjRef.trackStopTime(whichTrack);

Description

Digital video sprite property; returns the stop time of the specified track of the specified digital
video sprite.

When a digital video movie is played, trackStopTime is when playback halts or loops if the loop
property is turned on.

This property can be tested but not set.

Example

This statement determines the stop time of track 5 in the digital video assigned to sprite 6 and
displays the result in the Message window:

-- Lingo syntax
put(sprite(6).trackStopTime(5))

// JavaScript syntax
put(sprite(6).trackStopTime(5));

See also

playRate (QuickTime, AVI), currentTime (QuickTime, AVI), trackStartTime
(Member)

trackText

Usage

-- Lingo syntax
spriteObjRef.trackText(whichTrack)

// JavaScript syntax
spriteObjRef.trackText(whichTrack);

Description

Digital video sprite property; provides the text that is in the specified track of the digital video at
the current time. The result is a string value, which can be up to 32K characters long. This
property applies to text tracks only.

This property can be tested but not set.

Example

This statement assigns the text in track 5 of the digital video assigned at the current time to sprite
20 to the field cast member Archives:

-- Lingo syntax
member("Archives").text = string(sprite(20).trackText(5))

// JavaScript syntax
member("Archives").text = sprite(20).trackText(5).toString();
trackType (Member)

Usage

-- Lingo syntax
memberObjRef.trackType(whichTrack)

// JavaScript syntax
memberObjRef.trackType(whichTrack);

Description

Digital video cast member property; indicates which type of media is in the specified track of the specified cast member. Possible values are #video, #sound, #text, and #music.

This property can be tested but not set.

Example

The following handler checks whether track 5 of the digital video cast member Today's News is a text track and then runs the handler textFormat if it is:

-- Lingo syntax
on checkForText
  if member("Today's News").trackType(5) = #text then
    textFormat
  end if
end

// JavaScript syntax
function checkForText() {
  var tt = member("Today's News").trackType(5);
  if (tt = "text") {
    textFormat();
  }
}

trackType (Sprite)

Usage

-- Lingo syntax
spriteObjRef.trackType(whichTrack)

// JavaScript syntax
spriteObjRef.trackType(whichTrack);

Description

Digital video sprite property; returns the type of media in the specified track of the specified sprite. Possible values are #video, #sound, #text, and #music.

This property can be tested but not set.

Example

The following handler checks whether track 5 of the digital video sprite assigned to channel 10 is a text track and runs the handler textFormat if it is:

-- Lingo syntax
on checkForText
  if sprite(10).trackType(5) = #text then
    textFormat
  end if
end

end
// JavaScript syntax
function checkForText() {
    var tt = sprite(10).trackType(5);
    if (tt == "text") {
        textFormat();
    }
}

trails

**Usage**

sprite(whichSprite).trails
the trails of sprite whichSprite

**Description**

Sprite property; for the sprite specified by `whichSprite`, turns the trails ink effect on (1 or `TRUE`) or off (0 or `FALSE`). For the value set by Lingo to last beyond the current sprite, the sprite must be a scripted sprite.

To erase trails, animate another sprite across these pixels or use a transition.

**Example**

This statement turns on trails for sprite 7:

```
sprite(7).trails = 1
```

**See also**

directToStage

transform (property)

**Usage**

member(whichCastmember).node(whichNode).transform
member(whichCastmember).node(whichNode).transform.transform.

**Property**

member(whichCastmember).model(whichModel).bonesPlayer.
bone[boneID].transform
member(whichCastmember).model(whichModel).bonesPlayer.
bone[boneID].transform.transformProperty

**Description**

3D property and command; allows you to get or set the transform associated with a particular node or a specific bone within a model using the `bonesPlayer` modifier. As a command, `transform` provides access to the various commands and properties of the transform object. A node can be a camera, group, light or model object.

For node objects, this property defaults to the identity transform. A node's transform defines the position, rotation and scale of the node relative to its parent object. If a node's parent is the World group object, then the `transform` property of the node has the same value as is returned by the `getWorldTransform()` command.
For bones within models using the bonesPlayer modifier, this property defaults in value to the transform assigned to the bone upon creation of the model file. The transform of a bone represents the bone's rotation relative to its parent bone and its position relative to its original joint position. The original joint position is determined upon creation of the model file.

You can use the following transform commands and properties with the transform property of node objects:

Note: This section only contains summaries, see the individual entries for more detailed information.

- **preScale** applies scaling before the current positional, rotational, and scale offsets held by the transform.
- **preTranslate** applies a translation before the current positional, rotational, and scale offsets held by the transform.
- **preRotate** applies a rotation before the current positional, rotational, and scale offsets held by the transform.
- **scale**(command) applies scaling after the current positional, rotational, and scale offsets held by the transform.
- **scale**(transform) allows you to get or set the degree of scaling of the transform.
- **translate** applies a translation after the current positional, rotational, and scale offsets held by the transform.
- **rotate** applies a rotation after the current positional, rotational, and scale offsets held by the transform.
- **position**(transform) allows you to get or set the positional offset of the transform.
- **rotation**(transform) allows you to get or set the rotational offset of the transform.

If you want to modify the transform property of a bone within a model, then you must store a copy of the original transform of the bone, modify the stored copy using the above commands and properties, then reset the bone's transform property so that it is equal to the modified transform. For example:

```lingo
t = member("character").model("biped").bonesPlayer.bone[38].transform.duplicate()
t.translate(25,0,-3)
member("character").model("biped").bonesPlayer.bone[38].transform = t
```

Parameters

None.

Example

This Lingo shows the transform of the model box, followed by the position and rotation properties of the transform:

```lingo
put member("3d world").model("box").transform
-- transform(1.000000,0.000000,0.000000,0.000000, \ 
  0.000000,1.000000,0.000000,0.000000, \ 
  0.000000,0.000000,1.000000,0.000000, -\ 
  94.144844,119.012825,0.000000,1.000000)
put member("3d world").model("box").transform.position
-- vector(-94.1448, 119.0128, 0.0000)
put member("3d world").model("box").transform.rotation
-- vector(0.0000, 0.0000, 0.0000)
```
See also

 interpolateTo(), scale (transform), rotation (transform), position (transform), bone, worldTransform, preRotate, preScale(), preTranslate()

**transitionType**

**Usage**

```lingo
member(whichCastMember).transitionType
the transitionType of member whichCastMember
```

**Description**

Transition cast member property; determines a transition's type, which is specified as a number. The possible values are the same as the codes assigned to transitions for the puppetTransition command.

**Example**

This statement sets the type of transition cast member 3 to 51, which is a pixel dissolve cast member:

```lingo
member(3).transitionType = 51
```

**transitionXtraList**

**Usage**

```
-- Lingo syntax
_player.transitionXtraList

// JavaScript syntax
_player.transitionXtraList;
```

**Description**

Player property; returns a linear list of all transition Xtra extensions available to the Director player. Read-only.

**Example**

This statement displays in the Message window all available transition Xtra extensions.

```
-- Lingo syntax
put(_player.transitionXtraList)

// JavaScript syntax
put(_player.transitionXtraList);
```

See also

mediaXtraList, Player, scriptingXtraList, toolXtraList, xtraList (Player)
translation

Usage

-- Lingo syntax
memberOrSpriteObjRef.translation

// JavaScript syntax
memberOrSpriteObjRef.translation;

Description

QuickTime cast member and sprite property; controls the offset of a QuickTime sprite's image within the sprite's bounding box.

This offset is expressed in relation to the sprite's default location as set by its center property. When center is set to TRUE, the sprite is offset relative to the center of the bounding rectangle; when center is set to FALSE, the sprite is offset relative to the upper left corner of the bounding rectangle.

The offset, specified in pixels as positive or negative integers, is set as a Director list: [xTrans, yTrans]. The xTrans parameter specifies the horizontal offset from the sprite's default location; the yTrans parameter specifies the vertical offset. The default setting is [0,0].

When the sprite's crop property is set to TRUE, the translation property can be used to mask portions of the QuickTime movie by moving them outside the bounding rectangle. When the crop property is set to FALSE, the translation property is ignored, and the sprite is always positioned at the upper left corner of the sprite's rectangle.

This property can be tested and set.

Example

The following frame script assumes that the center property of the cast member of a 320-pixel-wide QuickTime sprite in channel 5 is set to FALSE, and its crop property is set to TRUE. It keeps the playhead in the current frame until the movie's horizontal translation point has moved to the right edge of the sprite, in 10-pixel increments. This has a wipe right effect, moving the sprite out of view to the right. When the sprite is out of view, the playhead continues to the next frame.

-- Lingo syntax
on exitFrame
    horizontalPosition = sprite(5).translation[1]
    if horizontalPosition < 320 then
        sprite(5).translation = sprite(5).translation + [10, 0]
        _movie.go(_movie.frame)
    end if
end

// JavaScript syntax
function exitFrame() {
    var horizontalPosition = sprite(5).translation[1];
    if (horizontalPosition < 320) {
        sprite(5).translation = sprite(5).translation + list(10, 0);
        _movie.go(_movie.frame);
    }
}
transparent

Usage

member(whichCastmember).shader(whichShader).transparent
member(whichCastmember).model(whichModel).shader.transparent
member(whichCastmember).model(whichModel).shaderList[shaderListIndex].transparent

Description

3D standard shader property; lets you get or set whether a model is blended using alpha values (TRUE) or is rendered as opaque (FALSE). The default value for this property is TRUE (alpha-blended).

The functionality of shader.blend is dependent upon this property.

All shaders have access to the #standard shader properties; in addition to these standard shader properties shaders of the types #engraver, #newsprint, and #painter have properties unique to their type. For more information, see the newShader.

Example

The following statement causes the model Pluto to be rendered opaque. The setting of the blend property for the model's shader will have no effect.

member("scene").model("Pluto").shader.transparent = FALSE

See also

blendFactor, blend (3D)

triggerCallback

Usage

-- Lingo syntax
spriteObjRef.triggerCallback

// JavaScript syntax
spriteObjRef.triggerCallback;

Description

QuickTime VR sprite property; contains the name of the handler that runs when the user clicks a hotspot in a QuickTime VR movie. The handler is sent two arguments: the me parameter and the ID of the hotspot that the user clicked.

The value that the handler returns determines how the movie processes the hotspot. If the handler returns #continue, the QuickTime VR sprite continues to process the hotspot normally. If the handler returns #cancel, the default behavior for the hotspot is canceled.

Set this property to 0 to clear the callback.

The QuickTime VR sprite receives the message first.

To avoid a decrease in performance, set the triggerCallback property only when necessary.

This property can be tested and set.
Example

The following statement sets the callback handler for a QuickTime VR sprite to the handler named `MyHotSpotCallback` when the playhead first enters the sprite span. Every time that hotspot is triggered, the `MyHotSpotCallback` handler is executed. When the playhead leaves the sprite span, the callback is canceled.

-- Lingo syntax

    property pMySpriteNum, spriteNum

    on beginSprite(me)
        pMySpriteNum = spriteNum
        sprite(pMySpriteNum).triggerCallback = #MyHotSpotCallback
    end

    on MyHotSpotCallback(me, hotSpotID)
        put "Hotspot" && hotSpotID && " was just triggered"
    end

    on endSprite me
        sprite(pMySpriteNum).triggerCallback = 0
    end

    // JavaScript syntax

    function beginSprite() {
        pMySpriteNum = this.spriteNum;
        sprite(this.pMySpriteNum).triggerCallback = symbol("MyHotSpotCallback");
    }

    function MyHotSpotCallback(hotSpotID) {
        trace("Hotspot " + hotSpotID + " was just triggered");
    }

    function endSprite() {
        sprite(pMySpriteNum).triggerCallback = 0;
    }

trimWhiteSpace

Usage

-- Lingo syntax

    memberObjRef.trimWhiteSpace

    // JavaScript syntax

    memberObjRef.trimWhiteSpace;

Description

Cast member property. Determines whether the white pixels around the edge of a bitmap cast member are removed or left in place. This property is set when the member is imported. It can be changed in Lingo or in the Bitmap tab of the Property inspector.
tunnelDepth

Usage
member(whichTextmember).tunnelDepth
member(whichCastMember).modelResource(whichExtruderModel\Resource).tunnelDepth

Description
A 3D extruder model resource property, as well as a text cast member property. Using this property allows you to get or set the extrusion depth (the distance between the front and back faces) of a 3D text model resource. Possible values are floating point numbers between 1.0 and 100.0. The default value is 50.0.

It is recommended that you see extrudeToMember entry for more information about working with extruder model resources and text cast members.

Example
In this example, the cast member logo is a text cast member. The following statement sets the tunnelDepth of logo to 5. When logo is displayed in 3D mode, its letters will be very shallow.
member("logo").tunnelDepth = 5

In this example, the model resource of the model Slogan is extruded text. The following statement sets the tunnelDepth of Slogan's model resource to 1000. Slogan's letters will be extremely deep.
member("scene").model("Slogan").resource.tunnelDepth = 1000

See also
extrude3D
tweened

Usage
sprite(whichSprite).tweened
the tweened of sprite whichSprite

Description
Sprite property; determines whether only the first frame in a new sprite is created as a keyframe (TRUE), or whether all frames in the new sprite are created as keyframes (FALSE).

This property does not affect playback and is useful only during Score recording.

This property can be tested and set.

Example
When this statement is issued, newly created sprites in channel 25 have a keyframe only in the first frame of the sprite span:
sprite(25).tweened = 1
**tweenMode**

**Usage**

member(whichCastmember).modelResource(whichModelResource).tweenMode
modelResourceObjectReference.tweenMode

**Description**

3D particle property; allows you to get or set whether the color of a particle varies according to its speed or age. The tweenMode property can have the following values:

- **#velocity** alters the color of the particle between colorRange.start and colorRange.end based on the velocity of the particle.
- **#age** alters the color of the particle by linearly interpolating the color between colorRange.start and colorRange.end over the lifetime of the particle. This is the default setting for this property.

**Example**

In this example, ThermoSystem is a model resource of the type #particle. This statement sets the ThermoSystem's tweenMode to #velocity, so its slower particles will not reach the color specified by colorRange.end, while its faster particles will:

```javascript
member(8,2).modelResource("thermoSystem").tweenMode = \
#velocitytype (light)
```

**type (light)**

**Usage**

member(whichCastmember).light(whichLight).type

**Description**

3D light property; the light type of the referenced light. This property's possible values are as follows:

- **#ambient** lights of this type cast their light evenly on all surfaces. The intensity of ambient lights is not affected by distance from the light source.
- **#directional** lights appear to shine in a particular direction, but are not as focused as lights of type #spot. The intensity of directional lights decreases with distance from the light source.
- **#point** lights shine in all directions from a specific location in the 3D world. The effect is similar to a bare light bulb hanging in a room. The intensity of point lights decreases with distance from the light source.
- **#spot** Lights of this type cast their light from a particular point and within the cone defined by the light's forward direction and spotAngle property. The intensity of spot lights declines with distance from the light source using the values defined in the light's attenuation property.

**Example**

The following statement displays the type property of the light named MainLight:

```javascript
put member("3D").motion("MainLight").type
-- #spot
```

**See also**

spotAngle, attenuation
type (Member)

Usage
-- Lingo syntax
memberObjRef.type

// JavaScript syntax
memberObjRef.type;

Description
Member property; indicates a cast member’s type. Read-only.
The type property can be one of the following values:

<table>
<thead>
<tr>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>#animgif</td>
<td>#ole</td>
</tr>
<tr>
<td>#bitmap</td>
<td>#palette</td>
</tr>
<tr>
<td>#button</td>
<td>#picture</td>
</tr>
<tr>
<td>#cursor</td>
<td>#QuickTimeMedia</td>
</tr>
<tr>
<td>#digitalVideo</td>
<td>#realMedia</td>
</tr>
<tr>
<td>#DVR</td>
<td>#script</td>
</tr>
<tr>
<td>#empty</td>
<td>#shape</td>
</tr>
<tr>
<td>#field</td>
<td>#shockwave3D</td>
</tr>
<tr>
<td>#filmloop</td>
<td>#sound</td>
</tr>
<tr>
<td>#flash</td>
<td>#swa</td>
</tr>
<tr>
<td>#flashcomponent</td>
<td>#text</td>
</tr>
<tr>
<td>#font</td>
<td>#transition</td>
</tr>
<tr>
<td>#havok</td>
<td>#vectorShape</td>
</tr>
<tr>
<td>#movie</td>
<td>#windowsMedia</td>
</tr>
</tbody>
</table>

This list includes those types of cast members that are available in Director and the Xtra extensions that come with it. You can also define custom cast member types for custom cast members.

For movies created in Director 5 and 6, the type property returns #field for field cast members and #richText for text cast members. However, field cast members originally created in Director 4 return #text for the member type, providing backward compatibility for movies that were created in Director 4.

Example
The following handler checks whether the cast member Today’s News is a field cast member and displays an alert if it is not:

-- Lingo syntax
on checkFormat
  if (member("Today’s News").type <> #field) then
    _player.alert("Sorry, this cast member must be a field.")
  end if
end

825
// JavaScript syntax
function checkFormat() {
    if (member("Today's News").type != "field") {
        _player.alert("Sorry, this cast member must be a field.");
    }
}

See also
Member

type (model resource)

Usage
member(whichCastmember).modelResource(whichModelResource).type

Description
3D model resource property; the resource type of the referenced model resource. This property’s possible values are:

- `#box` indicates that this model resource is a primitive box resource created using the `newModelResource` command.
- `#cylinder` indicates that this model resource is a primitive cylinder resource created using the `newModelResource` command.
- `#extruder` indicates that this model resource is a primitive text extruder resource created using the `extrude3d` command.
- `#mesh` indicates that this model resource is a primitive mesh generator resource created using the `newMesh` command.
- `#particle` indicates that this model resource is a primitive particle system resource created using the `newModelResource` command.
- `#plane` indicates that this model resource is a primitive plane resource created using the `newModelResource` command.
- `#sphere` indicates that this model resource is a primitive sphere resource created using the `newModelResource` command.
- `#fromFile` indicates that this model resource was created external to Director and was loaded from an external file or a cast member.

Example
The following statement displays the `type` property of the model resource named Helix.

```
put member("helix models").modelResource("Helix").type
-- #fromFile
```

See also
`newModelResource, newMesh, extrude3D`
**type (motion)**

**Usage**

`member(whichCastmember).motion(whichMotion).type`

**Description**

3D motion property; the motion type of the referenced motion object. This property's possible values are:

- `#bonesPlayer` indicates that this motion is a bones based animation and it requires the use of the `#bonesPlayer` modifier for playback.
- `#keyFramePlayer` indicates that this motion is a keyframed animation and it requires the use of the `#keyFramePlayer` modifier for playback.
- `#none` indicates that this motion has no mapped movement and it is suitable for use by either the `#bonesPlayer` or the `#keyFramePlayer` modifier for playback. The default motion object found in every 3D cast member is of this type.

**Example**

The following statement displays the `type` property of the motion named Run.

```plaintext
put member("scene").motion("Run").type
-- #bonesPlayer
```

The following statement displays the `type` property of the motion named DefaultMotion.

```plaintext
put member("scene").motion("DefaultMotion").type
-- #none
```

**See also**

`bonesPlayer (modifier), keyframePlayer (modifier)`

**type (shader)**

**Usage**

`member(whichCastmember).shader(whichShader).type`

**Description**

3D shader property; the shader type of the referenced shader object. This property's possible values are:

- `#standard` indicates that this is a standard shader.
- `#painter` indicates that this is a painter shader.
- `#newsprint` indicates that this is a newsprint shader.
- `#engraver` indicates that this is an engraver shader.

**Example**

This statement shows that the shader used by the model named box2 is a painter shader:

```plaintext
put member("Scene").model("box2").shader.type
-- #painter
```

**See also**

`newShader`
type (sprite)

Usage

sprite(whichSprite).type
the type of sprite whichSprite

Description

Sprite property; clears sprite channels during Score recording by setting the type sprite property value for that channel to 0.

Note: Switch the member of a sprite only to another member of the same type to avoid changing the sprite's properties when the member type is switched.

This property can be tested and set.

Example

This statement clears sprite channel 1 when issued during a Score recording session:

sprite(1).type = 0

type (texture)

Usage

member(whichCastmember).shader(whichShader).type

Description

3D texture property; the texture type of the referenced texture object. This property's possible values are:

- #fromCastMember indicates that this is texture was created from a Director cast member supporting the image property using the newTexture command.
- #fromImageObject indicates that this texture was created from an image object using the newTexture command.
- #importedFromFile indicates that this texture was created external to Director and created upon file import or cast member loading.

Example

This statement shows that the texture used by the shader for the model named Pluto was created from an image object:

put member("scene").model("Pluto").shader.texture.type
-- #fromImageObject

See also

newTexture
**type (Window)**

**Usage**

```-- Lingo syntax
windowObjRef.type
```

```// JavaScript syntax
windowObjRef.type;
```

**Description**

Window property; specifies the window type. Read/write.

If the `type` property is set, all properties pertaining to the new window are set accordingly.

This property can be one of the following values:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#document</td>
<td>Specifies that the window will appear with a standard title bar, a close box, a minimize box, and a maximize box. These types of windows can be moved.</td>
</tr>
<tr>
<td>#tool</td>
<td>Specifies that the window will appear with a shorter title bar and only a small close box in the upper right corner. These types of windows no longer receive activate or deactivate events, because #tool windows are always active. These types of windows will always later with each other, and will always appear on top of #document windows.</td>
</tr>
<tr>
<td>#dialog</td>
<td>Specifies that the window will appear with a standard title bar, a close box, and no icon. These types of windows are modal, and will always appear on top of all other windows.</td>
</tr>
</tbody>
</table>

These properties can also be accessed by using the Movie object’s `displayTemplate` property. Window behaviors also depend on the values of the `type` property and the Movie object's `dockingEnabled` property:

- If `dockingEnabled` is `TRUE` and `type` is set to `#document`, the MIAW will look and act like a document window in Director. The window will appear in the “view port” area and be dockable with the Stage, Score, and Cast windows, media editors, and message windows. However, the window will not be able to group with any of these windows.
- If `dockingEnabled` is `TRUE` and `type` is set to `#tool`, the MIAW will look and act like a tool window in Director. The window will be able to group with all tool windows except the Property inspector and the Tool palette.
- If `dockingEnabled` is `TRUE` and `type` is set to `#fullscreen` or `#dialog`, the type is ignored and the window will be an authoring window.

**Example**

This statement sets the type of the window named `Planets` to `#tool`.

```-- Lingo syntax
window("Planets").type = #tool
```

```// JavaScript syntax
window("Planets").type = "tool";
```

**See also**

`appearanceOptions, displayTemplate, dockingEnabled, titlebarOptions, Window`
**updateLock**

**Usage**

```-- Lingo syntax
_movie.updateLock
```  
```
// JavaScript syntax
_movie.updateLock;
```

**Description**

Movie property; determines whether the Stage is updated during Score recording (`FALSE`) or not (`TRUE`). Read/write.

You can keep the Stage display constant during a Score recording session by setting `updateLock` to `TRUE` before script updates the Score. If `updateLock` is `FALSE`, the Stage updates to show a new frame each time the frame is entered.

You can also use `updateLock` to prevent unintentional Score updating when leaving a frame, such as when you temporarily leave a frame to examine properties in another frame.

Although this property can be used to mask changes to a frame during run time, be aware that changes to field cast members appear immediately when the content is modified, unlike changes to location or members with other sprites, which are not updated until this property is turned off.

**See also**

`Movie`

**updateMovieEnabled**

**Usage**

```the updateMovieEnabled
```

**Description**

System property; specifies whether changes made to the current movie are automatically saved (`TRUE`) or not saved (`FALSE`, default) when the movie branches to another movie.

This property can be tested and set.

**Example**

This statement instructs Director to save changes to the current movie whenever the movie branches to another movie:

```the updateMovieEnabled = TRUE```

1058   Chapter 14: Properties
**URL**

**Usage**

-- Lingo syntax
memberObjRef.URL

// JavaScript syntax
memberObjRef.URL;

**Description**

Cast member property; specifies the URL for Shockwave Audio (SWA) and Flash movie cast members.

For Flash movie members, this property is synonymous with the **pathName** member property. The **URL** property can be tested and set. For SWA members, it can be set only when the SWA streaming cast member is stopped.

**Example**

This statement makes a file on an Internet server the URL for SWA cast member Benny Goodman:

-- Lingo syntax
on mouseDown
    member("Benny Goodman").URL = "http://audio.macromedia.com/samples/classic.swa"
end

// JavaScript syntax
function mouseDown() {
    member("Benny Goodman").URL = "http://audio.macromedia.com/samples/classic.swa"
}

**useAlpha**

**Usage**

-- Lingo syntax
memberObjRef.useAlpha
imageObjRef.useAlpha

// JavaScript syntax
memberObjRef.useAlpha;
imageObjRef.useAlpha;

**Description**

Bitmap cast member and image object property; for 32-bit cast members and image objects with alpha channel information, determines whether Director uses the alpha information when drawing the image onto the Stage (**true**), or whether Director ignores the alpha information when drawing to the Stage (**false**).
Example

This toggles the alpha channel of cast member “foreground” on and off:

```-- Lingo syntax
member("foreground").useAlpha = not(member("foreground").useAlpha)
```

```// JavaScript syntax
switch(member("foreground").useAlpha) {
    case 0:
        member("foreground").useAlpha = 1;
        break;
    case 1:
        member("foreground").useAlpha = 0;
        break;
}
```

useDiffuseWithTexture

Usage

```member(whichCastmember).shader(whichShader).useDiffuseWithTexture```

Description

3D standard shader property; allows you to get or set whether the diffuse color is used to modulate the texture (TRUE) or not (FALSE).

When set to TRUE, this property works in conjunction with the `blendFunction` and `blendConstant` properties: when `blendFunction` is set to #blend, the diffuse color is weighed with the texture color to determine the final color. For example, if `blendFunction` is set to #blend, and `blendConstant` is set to 100.0, the final color is the pure texture color. If we change `blendConstant` to 0.0, the final color is the diffuse color. If we change `blendConstant` to 10.0, the final color is 10% texture color, and 90% diffuse color.

The default value for this property is FALSE.

All shaders have access to the #standard shader properties; in addition to these standard shader properties shaders of the types #engraver, #newsprint, and #painter have properties unique to their type. For more information, see newShader.

Example

In this example, the `shaderList` of the model MysteryBox contains six shaders. Each shader has a texture list which contains up to eight textures. The `diffuseColor` property of the cast member (Level2) is set to rgb(255, 0, 0). The `blendFunction` property of all six shaders is set to #blend, and the `blendConstant` property of all six shaders is set to 80. This statement sets the `useDiffuseWithTexture` property of all shaders used by MysteryBox to TRUE. A little bit of red will be blended into the surface of the model. This property is affected by the settings of the `blendFunction`, `blendFunctionList`, `blendSource`, `blendSourceList`, `blendConstant`, and `blendConstantList` properties.

```member("Level2").model("MysteryBox").shaderlist.useDiffuseWithTexture = TRUE```

See also

`blendFunction`, `blendConstant`
**useFastQuads**

**Usage**

--- Lingo syntax
_movie.useFastQuads

// JavaScript syntax
_movie.useFastQuads;

**Description**

Movie property; determines whether to use faster (TRUE) or slower (FALSE, default) quad calculation operations. Read/write.

When set to TRUE, Director uses a faster, less precise method for calculating quad operations. Fast quads calculations are good for simple rotation and skew sprite effects.

When set to FALSE, Director uses the slower, default quad calculation method that provides more visually pleasing results when using quads for distortion and other arbitrary effects.

Simple sprite rotation and skew operations always use the fast quad calculation method, regardless of this setting. Setting useFastQuads to TRUE will not result in an increase in the speed of these simple operations.

**Example**

This statement tells Director to use its faster quad calculation code for all quad operations in the movie:

--- Lingo syntax
_movie.useFastQuads = TRUE

// JavaScript syntax
_movie.useFastQuads = true;

**See also**

Movie

**useHypertextStyles**

**Usage**

--- Lingo syntax
memberObjRef.useHypertextStyles

// JavaScript syntax
memberObjRef.useHypertextStyles;

**Description**

Text cast member property; controls the display of hypertext links in the text cast member.

When useHypertextStyles is TRUE, all links are automatically colored blue with underlines, and the pointer (cursor) changes to a pointing finger when it is over a link.

Setting this property to FALSE turns off the automatic formatting and pointer change.
Example

This behavior toggles the formatting of hypertext on and off in text cast member “myText”:

```
--Lingo syntax
on mouseUp
    member("myText").usehypertextStyles = \
        not(member("myText").usehypertextStyles)
end

// JavaScript syntax
function mouseUp() {
    member("myText").usehypertextStyles = \
        !(member("myText").usehypertextStyles)
}
```

useLineOffset

Usage

```
member(whichCastmember).model(whichModel).toon.useLineOffset
member(whichCastmember).model(whichModel).inker.useLineOffset
```

Description

3D toon and inker modifier property; indicates whether the modifier’s lineOffset property is used by the modifier when it draws lines on the surface of the model.

The default value of this property is FALSE.

Example

The following statement sets the useLineOffset property of the toon modifier for the model named Teapot to FALSE. The toon modifier’s lineOffset property will have no effect.

```
member("tp").model("Teapot").toon.useLineOffset = FALSE
```

See also

lineOffset

userData

Usage

```
member(whichCastmember).model(whichModel).userData
member(whichCastmember).light(whichLight).userData
member(whichCastmember).camera(whichCamera).userData
member(whichCastmember).group(whichCamera).userData
```

Description

3D property; returns the userData property list of a model, group, camera, or light. The default value of this property for an object that was created outside of Director is a list of all the properties that were assigned to the model’s userData property in the 3D modeling tool. The default value of this property for objects created inside of Director is an empty property list [], unless the object was created using any of the clone commands. If a cloning command was used to create the object then the new object’s userData property defaults to a value equal to that of the original source object.
To modify the elements of this list you must use the `addProp` and `deleteProp` commands documented in the main Lingo Dictionary.

**Example**

This statement displays the `userData` property of the model named `New Body`:

```
put member("Car").model("New Body").userData
-- [#driver: "Bob", #damage: 34]
```

This statement adds the property `#health` with the value 100 to the `userData` property list for the model named `Player`:

```
member("scene").model("Player").userData.addProp(#health,100)
```

**userName**

**Usage**

```
-- Lingo syntax
_player.userName

// JavaScript syntax
_player.userName;
```

**Description**

Player property; a string containing the user name entered when Director was installed. Read-only.

This property is available in the authoring environment only. It could be used in a movie in a window (MIAW) tool that is personalized to show the user’s information.

**Example**

The following handler places the user's name and serial number in a display field when the window is opened. (A movie script in the MIAW is a good location for this handler.)

```
-- Lingo syntax
on prepareMovie
    displayString = _player.userName & RETURN & _player.organizationName & RETURN & _player.serialNumber
    member("User Info").text = displayString
end

// JavaScript syntax
function prepareMovie() {
    var displayString = _player.userName + "\n" + _player.organizationName + "\n" + _player.serialNumber;
    member("User Info").text = displayString;
}
```

**See also**

Player
userName (RealMedia)

Usage

-- Lingo syntax
memberOrSpriteObjRef.userName

// JavaScript syntax
memberOrSpriteObjRef.userName;

Description

RealMedia sprite and cast member property; allows you to set the user name required to access a protected RealMedia stream. For security reasons, you cannot use this property to retrieve a previously specified user name. If a user name has been set, the value of this property is the string "********". The default value of this property is an empty string, which means no user name has been specified.

Example

The following examples show that the user name for the RealMedia stream in the cast member Real or sprite 2 has been set.

-- Lingo syntax
put(sprite(2).userName) -- "********"
put(member("Real").userName) -- "********"

// JavaScript syntax
put(sprite(2).userName); // "********"
put(member("Real").userName); // "********"

The following examples show that the user name for the RealMedia stream in the cast member Real or sprite 2 has never been set.

-- Lingo syntax
put(sprite(2).userName) -- ""
put(member("Real").userName) -- ""

// JavaScript syntax
put(sprite(2).userName); // ""
put(member("Real").userName); // ""

The following examples set the user name for the RealMedia stream in the cast member Real and sprite 2 to Marcelle.

-- Lingo syntax
member("Real").userName = "Marcelle"
sprite(2).userName = "Marcelle"

// JavaScript syntax
member("Real").userName = "Marcelle";
sprite(2).userName = "Marcelle";

See also

password
useTargetFrameRate

Usage

sprite(which3dSprite).useTargetFrameRate

Description

3D sprite property; determines whether the targetFrameRate property of the sprite is enforced. If the useTargetFrameRate property is set to TRUE, the polygon count of the models in the sprite are reduced if necessary to achieve the specified frame rate.

Example

These statements set the targetFrameRate property of sprite 3 to 45 and enforce the frame rate by setting the useTargetFrameRate property of the sprite to TRUE:

sprite(3).targetFrameRate = 45
sprite(3).useTargetFrameRate = TRUE

See also

targetFrameRate

vertex

Usage

-- Lingo syntax
memberObjRef.vertex[whichVertexPosition]

// JavaScript syntax
memberObjRef.vertex[whichVertexPosition];

Description

Chunk expression; enables direct access to parts of a vertex list of a vector shape cast member. Use this chunk expression to avoid parsing different chunks of the vertex list. It’s possible to both test and set values of the vertex list using this type of chunk expression.

Example

The following code shows how to determine the number of vertex points in a member:

-- Lingo syntax
put(member("Archie").vertex.count) -- 2

// JavaScript syntax
put(member("Archie").vertex.count); // 2

To obtain the second vertex for the member, you can use code like this:

-- Lingo syntax
put(member("Archie").vertex[2]) -- point(66.0000, -5.0000)

// JavaScript syntax
put(member("Archie").vertex[2]); // point(66.0000, -5.0000)

You can also set the value in a control handle:

-- Lingo syntax
member("Archie").vertex[2].handle1 = point(-63.0000, -16.0000)
vertexList

Usage
-- Lingo syntax
memberObjRef.vertexList

// JavaScript syntax
memberObjRef.vertexList;

Description
Cast member property; returns a linear list containing property lists, one for each vertex of a vector shape. The property list contains the location of the vertex and the control handle. There are no control handles if the location is (0,0).

Each vertex can have two control handles that determine the curve between this vertex and the adjacent vertices. In vertexList, the coordinates of the control handles for a vertex are kept relative to that vertex, rather than absolute in the coordinate system of the shape. If the first control handle of a vertex is located 10 pixels to the left of that vertex, its location is stored as (-10, 0). Thus, when the location of a vertex is changed with Lingo, the control handles move with the vertex and do not need to be updated (unless the user specifically wants to change the location or size of the handle).

When modifying this property, be aware that you must reset the list contents after changing any of the values. This is because when you set a variable to the value of the property, you are placing a copy of the list, not the list itself, in the variable. To effect a change, use code like this:

- Get the current property contents
  currVertList = member(1).vertexList
- Add 25 pixels to the horizontal and vertical positions of the first vertex in the list
  currVertList[1].vertex = currVertList[1].vertex + point(25, 25)
- Reset the actual property to the newly computed position
  member(1).vertexList = currVertList

Example
This statement displays the vertexList value for an arched line with two vertices:

-- Lingo syntax
put(member("Archie").vertexList)
  -- [[#vertex: point(-66.0000, 37.0000), #handle1: point(-70.0000, -36.0000), #handle2: point(-62.0000, 110.0000)], [#vertex: point(66.0000, -5.0000), #handle1: point(121.0000, 56.0000), #handle2: point(11.0000, -66.0000)]]

// JavaScript syntax
put(member("Archie").vertexList);
  //[[#vertex: point(-66.0000, 37.0000), #handle1: point(-70.0000, -36.0000), #handle2: point(-62.0000, 110.0000)], [#vertex: point(66.0000, -5.0000), #handle1: point(121.0000, 56.0000), #handle2: point(11.0000, -66.0000)]]

See also
addVertex(), count(), deleteVertex(), moveVertex(), moveVertexHandle(), originMode, vertex
vertexList (mesh generator)

Usage

member(whichCastmember).modelResource(whichModelResource).vertexList

Description

3D property; when used with a model resource whose type is #mesh, allows you to get or set the vertexList property for the model resource.

The vertexList is a linear list of each vertex used in the mesh. A single vertex may be shared by numerous faces of the mesh. You can specify a list of any size for this property, but it will store only the number of items specified when using the newMesh() command to create the #mesh model resource.

Example

This statement sets the vertexList of the model resource named Triangle:

member("Shapes").modelResource("Triangle").vertexList = \[vector(0,0,0), vector(20,0,0), vector(20, 20, 0)\]

See also

newMesh, face, vertices

vertexList (mesh deform)

Usage

member(whichCastmember).model(whichModel).meshDeform.mesh\[index].vertexList

Description

3D property; when used with a model with the #meshDeform modifier attached, it allows you to get or set the vertexList property for the specified mesh within the referenced model.

The vertexList is a linear list of each vertex used in the specified mesh. A single vertex may be shared by numerous faces of the mesh.

If a model makes use of the #sds or #lod modifiers in addition to the #meshDeform modifier, then it is important to know that the value of this property will change under the influence of the #sds or #lod modifiers.

Example

This statement displays the #meshDeform modifier's vertexList for the first mesh in the model named Triangle:

put member("Shapes").model("Triangle").meshDeform.mesh[1].vertexList -- [vector(0,0,0), vector(20,0,0), vector(20, 20, 0)]

See also

face, vertices, mesh (property)
vertices

Usage

member(whichCastMember).modelResource(whichModelResource).
  face[faceIndex].vertices

Description

3D face property; when used with a model resource whose type is #mesh, this property allows you to get or set which vertices from the resource's vertexList property to use for the mesh face specified by faceIndex.

This property is a linear list of three integers corresponding to the index positions of the three vertices, as found in the mesh's vertexList property, that comprise the specified face.

The vertices must be specified in the list using counterclockwise winding in order to achieve an outward pointing surface normal.

If you make changes to this property or use the generateNormals() command, you will need to call the build() command in order to rebuild the mesh.

Example

This example displays the vertexList of the mesh model resource named SimpleSquare, then it displays the vertices property for the second face of that mesh:

put member("3D").modelResource("SimpleSquare").vertexList
-- [vector( 0.0000, 0.0000, 0.0000), vector( 0.0000, 5.0000, \
 0.0000), vector( 5.0000, 0.0000, 0.0000), vector( 5.0000, \n 5.0000, 0.0000)]
put member("3D").modelResource("SimpleSquare").face[1].vertices
-- [3, 4, 1]

See also

face, vertexList (mesh deform), generateNormals()

video (QuickTime, AVI)

Usage

member(whichCastMember).video
the video of member whichCastMember

Description

Digital video cast member property; determines whether the graphic image of the specified digital video cast member plays (TRUE or 1) or not (FALSE or 0).

Only the visual element of the digital video cast member is affected. For example, when video is set to FALSE, the digital video's soundtrack, if present, continues to play.

Example

This statement turns off the video associated with the cast member Interview:

member("Interview").video = FALSE

See also

setTrackEnabled(), trackEnabled
video (RealMedia, Windows Media)

Usage
--- Lingo syntax
memberOrSpriteObjRef.video

// JavaScript syntax
memberOrSpriteObjRef.video;

Description
RealMedia and Windows Media property; allows you to set or get whether the sprite or cast member renders video (TRUE or 1) or only plays the sounds (FALSE or 0). Read/write.

Integer values other than 1 or 0 are treated as TRUE.

Use this property to suppress the video while playing the audio component of a RealMedia or Windows Media cast member, or to toggle the video on and off during playback.

Example
The following examples show that the video property for sprite 2 and the cast member Real is set to TRUE.

--- Lingo syntax
put(sprite(2).video) -- 1
put(member("Real").video) -- 1

// JavaScript syntax
put(sprite(2).video); // 1
put(member("Real").video); // 1

The following examples set the video property to FALSE for the RealMedia video element of sprite 2 and the cast member Real.

--- Lingo syntax
sprite(2).video = FALSE
member("Real").video = FALSE

// JavaScript syntax
sprite(2).video = 0;
membre("Real").video = 0;

videoFormat

Usage
--- Lingo syntax
dvdObjRef.videoFormat

// JavaScript syntax
dvdObjRef.videoFormat;

Description
DVD property. Returns a symbol that indicates the video format. Read-only.
Possible symbols include the following:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#MPEG1</td>
<td>The video format is MPEG-1.</td>
</tr>
<tr>
<td>#MPEG2</td>
<td>The video format is MPEG-2.</td>
</tr>
<tr>
<td>#unknown</td>
<td>The video format is unknown.</td>
</tr>
</tbody>
</table>

**videoForWindowsPresent**

**Usage**

```lingo
the videoForWindowsPresent
```

**Description**

System property; indicates whether AVI software is present on the computer.

This property can be tested but not set.

**Example**

This statement checks whether Video for Windows is missing and branches the playhead to the Alternate Scene marker if it isn’t:

```lingo
if the videoForWindowsPresent = FALSE then go to "Alternate Scene"
```

See also

[quickTimeVersion()](#)

**viewH**

**Usage**

```lingo
-- Lingo syntax
memberOrSpriteObjRef.viewH
```

```javascript
memberOrSpriteObjRef.viewH;
```

**Description**

Cast member and sprite property; controls the horizontal coordinate of a Flash movie and vector shape's view point, specified in pixel units. The values can be floating-point numbers. The default value is 0.

A Flash movie's view point is set relative to its origin point.

Setting a positive value for `viewH` shifts the movie to the left inside the sprite; setting a negative value shifts the movie to the right. Therefore, changing the `viewH` property can have the effect of cropping the movie or even of removing the movie from view entirely.

This property can be tested and set.

**Note:** This property must be set to the default value if the scaleMode property is set to #autoSize, or the sprite will not display correctly.
Example

This handler accepts a sprite reference as a parameter and moves the view of a Flash movie sprite from left to right within the sprite's bounding rectangle:

```lingo
on panRight whichSprite
  repeat with i = 120 down to -120
    sprite(whichSprite).viewH = i
    _movie.updateStage()
  end repeat
end
```

```javascript
function panRight(whichSprite) {
  var i = 120;
  while(i > -121) {
    sprite(whichSprite).viewH = i;
    _movie.updateStage();
    i--;
  }
}
```

See also

scaleMode, viewV, viewPoint, viewScale

viewPoint

Usage

```lingo
memberOrSpriteObjRef.viewPoint
```

```javascript
memberOrSpriteObjRef.viewPoint;
```

Description

Cast member property and sprite property; controls the point within a Flash movie or vector shape that is displayed at the center of the sprite's bounding rectangle in pixel units. The values are integers.

Changing the view point of a cast member changes only the view of a movie in the sprite's bounding rectangle, not the location of the sprite on the Stage. The view point is the coordinate within a cast member that is displayed at the center of the sprite's bounding rectangle and is always expressed relative to the movie's origin (as set by the originPoint, originH, and originV properties). For example, if you set a Flash movie's view point at point (100,100), the center of the sprite is the point within the Flash movie that is 100 Flash movie pixel units to the right and 100 Flash movie pixel units down from the origin point, regardless of where you move the origin point.

The viewPoint property is specified as a Director point value: for example, point (100,200). Setting a Flash movie's view point with the viewPoint property is the same as setting the viewH and viewV properties separately. For example, setting the viewPoint property to point (50,75) is the same as setting the viewH property to 50 and the viewV property to 75.
Director point values specified for the `viewPoint` property are restricted to integers, whereas `viewH` and `viewV` can be specified with floating-point numbers. When you test the `viewPoint` property, the point values are truncated to integers. As a general guideline, use the `viewH` and `viewV` properties for precision; use the `originPoint` property for speed and convenience.

This property can be tested and set. The default value is point (0,0).

**Note:** This property must be set to the default value if the `scaleMode` property is set to `#autoSize`, or the sprite will not display correctly.

**Example**

This handler makes a specified Flash movie sprite move down and to the right in increments of five Flash movie pixel units:

```
-- Lingo syntax
on panAcross(whichSprite)
  repeat with i = 1 to 10
    sprite(whichSprite).viewPoint = sprite(whichSprite).viewPoint + \point(i * -5, i * -5)
    _movie.updateStage()
  end repeat
end

// JavaScript syntax
function panAcross(whichSprite) {
  var i = 1;
  while(i < 11) {
    sprite(whichSprite).viewPoint = sprite(whichSprite).viewPoint + \point(i * -5, i * -5);
    _movie.updateStage();
    i++
  }
}
```

See also `scaleMode, viewV, viewH, viewScale`

**viewScale**

**Usage**

```
-- Lingo syntax
memberOrSpriteObjRef.viewScale

// JavaScript syntax
memberOrSpriteObjRef.viewScale;
```

**Description**

Cast member property and sprite property; sets the overall amount to scale the view of a Flash movie or vector shape sprite within the sprite's bounding rectangle. You specify the amount as a percentage using a floating-point number. The default value is 100.

The sprite rectangle itself is not scaled; only the view of the cast member within the rectangle is scaled. Setting the `viewScale` property of a sprite is like choosing a lens for a camera. As the `viewScale` value decreases, the apparent size of the movie within the sprite increases, and vice versa. For example, setting `viewScale` to 200% means the view inside the sprite will show twice the area it once did, and the cast member inside the sprite will appear at half its original size.
One significant difference between the viewScale and scale properties is that viewScale always scales from the center of the sprite’s bounding rectangle, whereas scale scales from a point determined by the Flash movie’s originMode property.

This property can be tested and set.

**Note:** This property must be set to the default value if the scaleMode property is set to #autoSize, or the sprite will not display correctly.

**Example**

This sprite script sets up a Flash movie sprite and doubles its view scale:

```
-- Lingo syntax
property spriteNum

on beginSprite me
  sprite(spriteNum).viewScale = 200
end

// JavaScript syntax
function beginSprite() {
  sprite(this.spriteNum).viewScale = 200;
}
```

**See also**

scaleMode, viewV, viewPoint, viewH

**viewV**

**Usage**

```
-- Lingo syntax
memberOrSpriteObjRef.viewV

// JavaScript syntax
memberOrSpriteObjRef.viewV;
```

**Description**

Cast member and sprite property; controls the vertical coordinate of a Flash movie and vector shape’s view point, specified in pixel units. The values can be floating-point numbers. The default value is 0.

A Flash movie’s view point is set relative to its origin point.

Setting a positive value for viewV shifts the movie up inside the sprite; setting a negative value shifts the movie down. Therefore, changing the viewV property can have the effect of cropping the movie or even of removing the movie from view entirely.

This property can be tested and set.

**Note:** This property must be set to the default value if the scaleMode property is set to #autoSize, or the sprite will not display correctly.
Example

This handler accepts a sprite reference as a parameter and moves the view of a Flash movie sprite from the top to the bottom within the sprite’s bounding rectangle:

```
-- Lingo syntax
on panDown(whichSprite)
    repeat with i = 120 down to -120
        sprite(whichSprite).viewV = i
        _movie.updateStage()
    end repeat
end

// JavaScript syntax
function panDown(whichSprite) {
    var i = 120;
    while(i > -121) {
        sprite(whichSprite).viewV = i;
        _movie.updateStage();
        i--;
    }
}
```

See also

`scaleMode, viewV, viewPoint, viewH`

visible

Usage

```
-- Lingo syntax
windowObjRef.visible

// JavaScript syntax
windowObjRef.visible;
```

Description

Window property; determines whether a window is visible (`TRUE`) or not (`FALSE`). Read/write.

Example

This statement makes the window named `Control_Panel` visible:

```
-- Lingo syntax
window("Control_Panel").visible = TRUE

// JavaScript syntax
window("Control_Panel").visible = true;
```

See also

`Window`
visible (sprite)

Usage

```javascript
sprite(whichSprite).visible = the visible of sprite whichSprite
```

Description

Sprite property; determines whether the sprite specified by `whichSprite` is visible (TRUE) or not (FALSE). This property affects all sprites in the channel, regardless of their position in the Score.

**Note:** Setting the `visible` property of a sprite channel to FALSE makes the sprite invisible and prevents only the mouse-related events from being sent to that channel. The `beginSprite`, `endSprite`, `prepareFrame`, `enterFrame`, and `exitFrame` events continue to be sent regardless of the sprite’s visibility setting. Clicking the Mute button on that channel in the Score, however, will set the `visible` property to FALSE and prevent all events from being sent to that channel. Muting disables a channel, while setting a sprite’s `visible` property to FALSE merely affects a graphic property.

This property can be tested and set. If set to FALSE, this property will not automatically reset to TRUE when the sprite ends. You must set the `visible` property of the sprite to TRUE in order to see any other members using that channel.

Example

This statement makes sprite 8 visible:

```javascript
sprite(8).visible = TRUE
```

visibility

Usage

```javascript
member(whichCastmember).model(whichModel).visibility
modelObjectReference.visibility
```

Description

3D property; allows you to get or set the `visibility` property of the referenced model. This property determines how the model’s geometry is drawn. It can have one of the following values:

- **#none** specifies that no polygons are drawn and the model is invisible.
- **#front** specifies that only those polygons facing the camera are drawn. This method is referred to as back face culling and optimizes rendering speed. This is the default setting for the property.
- **#back** specifies that only those polygons facing away from the camera are drawn. Use this setting when you want to draw the inside of a model, or for models which are not drawing correctly, possibly because they were imported from a file format that used a different handiness value when computing normals.
- **#both** specifies that both sides of all polygons are drawn. Use this setting when you want to see the plane regardless of the viewing direction, and for models that are not drawing correctly.

Example

The following statement shows that the visibility property of the model Monster02 is set to `#none`. The model is invisible.

```javascript
put member("3D").model("Monster02").visibility
-- #none
```
volume (DVD)

Usage
-- Lingo syntax
dvdObjRef.volume

// JavaScript syntax
dvdObjRef.volume;

Description
DVD property. Determines the current volume. Read/write.
The volume must be an integer in the range of 0 (silent) to 100 (full volume).

See also
DVD

volume (Member)

Usage
-- Lingo syntax
memberObjRef.volume

// JavaScript syntax
memberObjRef.volume;

Description
Shockwave Audio (SWA) cast member property; determines the volume of the specified SWA
streaming cast member. Values range from 0 to 255.
This property can be tested and set.

Example
This statement sets the volume of an SWA streaming cast member to half the possible volume:
-- Lingo syntax
member("SWAfile").volume = 128

// JavaScript syntax
member("SWAfile").volume = 128;

volume (Sound Channel)

Usage
-- Lingo syntax
soundChannelObjRef.volume

// JavaScript syntax
soundChannelObjRef.volume;

Description
Sound Channel property; determines the volume of a sound channel. Read/write.
Sound channels are numbered 1, 2, 3, and so on up to 8. Channels 1 and 2 are the channels that
appear in the Score.
The value of the `volume` property ranges from 0 (mute) to 255 (maximum volume). A value of 255 indicates the full volume set for the machine, as controlled by the Sound object's `soundLevel` property, and lower values are scaled to that total volume. This property allows several channels to have independent settings within the available range.

The lower the value of the `volume` sound property, the more static or noise you're likely to hear. Using `soundLevel` may produce less noise, although this property offers less control.

To see an example of `volume` used in a completed movie, see the Sound Control movie in the Learning/Lingo Examples folder inside the Director application folder.

**Example**

This statement sets the volume of sound channel 2 to 130, which is a medium sound level setting:

```-- Lingo syntax
sound(2).volume = 130

// JavaScript syntax
sound(2).volume = 130;
```

See also

`Sound Channel`, `soundLevel`

---

### volume (Sprite)

**Usage**

```-- Lingo syntax
spriteObjRef.volume

// JavaScript syntax
spriteObjRef.volume;
```

**Description**

Sprite property; controls the volume of a digital video movie or Windows Media cast member specified by name or number. The values range from 0 to 256. Values of 0 or less mute the sound. Values exceeding 256 are loud and introduce considerable distortion.

**Example**

This statement sets the volume of the QuickTime movie playing in sprite channel 7 to 256, which is the maximum sound volume:

```-- Lingo syntax
sprite(7).volume = 256

// JavaScript syntax
sprite(7).volume = 256;
```

See also

`soundLevel`
volume (Windows Media)

Usage

-- Lingo syntax
windowsMediaObjRef.volume

// JavaScript syntax
windowsMediaObjRef.volume;

Description

Windows Media sprite property; determines the volume of a Windows Media sprite. The value of this property is an integer that ranges from 0 (mute) to 7 (loud). You can also set this property using the Control > Volume menu in Director.

Example

This statement sets the volume of sprite 7 to 2:

-- Lingo syntax
sprite(7).volume = 2

// JavaScript syntax
sprite(7).volume = 2;

See also

Windows Media

warpMode

Usage

-- Lingo syntax
spriteObjRef.warpMode

// JavaScript syntax
spriteObjRef.warpMode;

Description

QuickTime VR sprite property; specifies the type of warping performed on a panorama. Possible values are #full, #partial, and #none.

This property can be tested and set. When tested, if the values for the static and motion modes differ, the property's value is the value set for the current mode. When set, the property determines the warping for both the static and motion modes.

Example

This sets the warpMode of sprite 1 to #full:

-- Lingo syntax
sprite(1).warpMode = #full

// JavaScript syntax
sprite(1).warpMode = symbol("full");
width

Usage

-- Lingo syntax
memberObjRef.width
imageObjRef.width
spriteObjRef.width

// JavaScript syntax
memberObjRef.width;
imageObjRef.width;
spriteObjRef.width;

Description

Member, Image, and Sprite property; for vector shape, Flash, animated GIF, RealMedia, Windows Media, bitmap, and shape cast members, determines the width, in pixels, of a cast member. Read-only for cast members and image objects, read/write for sprites.

This property does not affect field and button cast members.

Example

This statement assigns the width of member 50 to the variable theHeight:

-- Lingo syntax
theHeight = member(50).width

// JavaScript syntax
var theHeight = member(50).width;

This statement sets the width of sprite 10 to 26 pixels:

-- Lingo syntax
sprite(10).width = 26

// JavaScript syntax
sprite(10).width = 26;

This statement assigns the width of sprite number i + 1 to the variable howWide:

-- Lingo syntax
howWide = sprite(i + 1).width

// JavaScript syntax
var howWide = sprite(i + 1).width;

See also

height, image (Image), Member, Sprite
**width (3D)**

**Usage**

\[
\text{member(}\text{whichCastmember}).\text{modelResource(}\text{whichModelResource}).\text{width}
\]

\[
\text{modelResourceObjectReference.width}
\]

**Description**

3D property; allows you to get or set the width of the plane for a model resource whose type is \#box or \#plane. This property must be greater than 0.0, and has a default setting of 1.0. For objects whose type is \#box, the default value of width is 50.0. For objects whose type is \#plane, the default setting is 1.0. width is measured along the X axis.

**Example**

This statement sets the width of the model resource Grass plane to 250.0:

\[
\text{member(}\text{"3D World"}).\text{modelResource(}\text{"Grass plane"}).\text{width} = 250.0
\]

**widthVertices**

**Usage**

\[
\text{member(}\text{whichCastmember}).\text{modelResource(}\text{whichModelResource}).
\]

\[
\text{widthVertices}
\]

\[
\text{modelResourceObjectReference.widthVertices}
\]

**Description**

3D property; allows you to get or set the number of vertices (as an integer) on the X axis of a model resource whose type is \#box or \#plane. This property must be greater than or equal to 2, and has a default value of 2.

**Example**

The following statement sets the \text{widthVertices} property of the model resource Tower to 10. Eighteen polygons (2 * (10-1) triangles) will be used to define the geometry of the model resource along its x-axis.

\[
\text{member(}\text{"3D World"}).\text{modelResource(}\text{"Tower"}).\text{widthVertices} = 10
\]

**wind**

**Usage**

\[
\text{member(}\text{whichCastmember}).\text{modelResource(}\text{whichModelResource}).\text{wind}
\]

\[
\text{modelResourceObjectReference.wind}
\]

**Description**

3D property; allows you to get or set the \text{wind} property of a model resource whose type is \#particle, as a vector.

This \text{wind} property defines the direction and strength of the wind force applied to all particles during each simulation step. The default value for this property is vector(0, 0, 0), which specifies that no wind is applied.
Example
put member("3D").modelResource("fog bank").wind -- vector(10.5,0,0)

window

Usage
-- Lingo syntax
_player.window[windowNameOrNum]

// JavaScript syntax
_player.window[windowNameOrNum];

Description
Player property; provides indexed or named access to the Window objects created by the Director player. Read-only.

The windowNameOrNum argument is either a string that specifies the name of the window to access or an integer that specifies the index position of the window to access.

The functionality of this property is identical to the top level window() method.

Example
This statements sets the variable named myWindow to the third window object:

-- Lingo syntax
myWindow = _player.window[3]

// JavaScript syntax
var myWindow = _player.window[3];

See also
Player, window()

windowBehind

Usage
-- Lingo syntax
windowObjRef.windowBehind

// JavaScript syntax
windowObjRef.windowBehind;

Description
Window property; returns a reference to the window that is behind all other windows. Read-only.

Example
These statements set the variable backWindow to the window behind all other windows, and then moves that window to the front:

-- Lingo syntax
backWindow = _player.windowList[5].windowBehind
backWindow.moveToFront()
// JavaScript syntax
var backWindow = _player.windowList[5].windowBehind;
backWindow.moveToFront();

See also
moveToBack(), moveToFront(), Window, windowInFront, windowList

windowInFront

Usage
-- Lingo syntax
windowObjRef.windowInFront

// JavaScript syntax
windowObjRef.windowInFront;

Description
Window property; returns a reference to the window that is in front of all other windows. Read-only.

Example
These statements set the variable frontWindow to the window in front of all other windows, and then moves that window to the back:

-- Lingo syntax
frontWindow = _player.windowList[5].windowInFront
frontWindow.moveToBack()

// JavaScript syntax
var frontWindow = _player.windowList[5].windowInFront
frontWindow.moveToBack();

See also
moveToBack(), moveToFront(), Window, windowBehind, windowList

windowList

Usage
-- Lingo syntax
_player.windowList

// JavaScript syntax
_player.windowList;

Description
Player property; displays a list of references to all known movie windows. Read-only. The Stage is also considered a window.

Example
This statement displays in the Message window a list of all known movie windows:

-- Lingo syntax
trace(_player.windowList)
// JavaScript syntax
trace(_player.windowList);

See also
Player

wordWrap

Usage
- Lingo syntax
  memberObjRef.wordWrap

// JavaScript syntax
memberObjRef.wordWrap;

Description
Cast member property; determines whether line wrapping is allowed (TRUE) or not (FALSE).

Example
This statement turns line wrapping off for the field cast member Rokujo:

--Lingo syntax
member("Rokujo").wordWrap = FALSE

// JavaScript syntax
member("Rokujo").wordWrap = false;

worldPosition

Usage
member(whichCastmember).model(whichModel).worldPosition
member(whichCastmember).light(whichLight).worldPosition
member(whichCastmember).camera(whichCamera).worldPosition
member(whichCastmember).group(whichGroup).worldPosition

Description
3D property; allows you to get and not set the position of the specified node in world coordinates. A node can be a model, group, camera, or light. This property is equivalent in result to using getWorldTransform().position command. The position of a node is represented by a vector object.

Example
This statement shows that the position of the model named Mars, in world coordinates, is the vector (-1333.2097, 0.0000, -211.0973):

put member("scene").model("Mars").worldPosition
-- vector(-1333.2097, 0.0000, -211.0973)

See also
getWorldTransform(), position (transform)
**worldTransform**

**Usage**

member(whichMember).model(whichModel).bonesPlayer.bone[index].
worldTransform

**Description**

3D bonesplayer property; allows you to get the world relative transform of a specific bone, as opposed to using the transform property which returns the bone's parent relative transform. The worldTransform property can only be used with bonesplayer modified models.

**Example**

This statement stores a bone's world relative transform in the variable finalTransform:

```lua
finalTransform = member("3D").model("biped").bonesPlayer.bone[3].worldTransform
```

**See also**

`bone, getWorldTransform(), transform (property)`

**wrapTransform**

**Usage**

```lua
member( whichCastmember ).shader( ShaderName ).wrapTransform
member( whichCastmember ).shader[ ShaderIndex ].wrapTransform
member( whichCastmember ).model[ modelName ].shader.wrapTransform
member( whichCastmember ).model.shaderlist[ shaderListIndex ].
wrapTransform
```

**Description**

3D standard shader property; this property provides access to a transform that modifies the texture coordinate mapping for the shader's texture. Rotate this transform to alter how the texture is projected onto a model surface. The texture remains unaffected; the transform modifies only the orientation of how the shader applies the texture.

**Note**

Note: This command only has an effect when the shader's textureModeList is set to is #planar, #spherical, or #cylindrical.

**Example**

These statements set the transformMode of the shader named "shad2" to #wrapCylindrical, then rotates that cylindrical projection by 90° about the x-axis so that the cylindrical mapping wraps around the y-axis instead of the z-axis:

```lua
s = member("Scene").shader("shad2")
s.textureMode= #wrapCylindrical
s.wrapTransform.rotate(90.0, 0.0, 0.0)
```
wrapTransformList

Usage
member( whichCastmember ).shader( ShaderName ).wrapTransformList[ textureLayerIndex ]
member( whichCastmember ).shaderList[ shaderListIndex ].
  wrapTransformList[ textureLayerIndex ]
member( whichCastmember ).model( modelName ).
  shader.wrapTransformList[ textureLayerIndex ]
member( whichCastmember ).model( modelName ).shaderList[ shaderListIndex ]. wrapTransformList[ textureLayerIndex ]

Description
3D standard shader property; this property provides access to a transform that modifies the texture coordinate mapping of a specified texture layer. Rotate this transform to alter how the texture is projected onto model surfaces. The texture itself remains unaffected; the transform modifies only the orientation of how the shader applies the texture.

Note: wrapTransformList[textureLayerIndex] only has an effect when textureModeList[textureLayerIndex] is set to #planar, #spherical, or #cylindrical.

Example
In this example, line 2 sets the transformMode of the third texture layer of the shader named "shad2" to #wrapCylindrical. Line 3 rotates that cylindrical projection by 90° about the x-axis so that the cylindrical mapping wraps around the y-axis instead of the z-axis.

s = member("Scene").shader("shad2")
s.textureModeList[3] = #WrapCylindrical
s.wrapTransformList[3].rotate(90.0, 0.0, 0.0)

See also
newShader, textureModeList

x (vector)

Usage
member( whichCastmember ).vector.x
member( whichCastmember ).vector[1]

Description
3D property; allows you to get or set the x component of a vector.

Example
This statement shows the x component of a vector:

vec = vector(20, 30, 40)
put vec.x
-- 20.0000
**xAxis**

**Usage**

member(whichCastmember).transform.xAxis

**Description**

3D transform property; allows you to get but not set the vector representing the transform's canonical x-axis in transform space.

**Example**

The first line of this example sets the transform of the model ModCylinder to the identity transform. The next two lines show that the x-axis of ModCylinder is the vector (1.0000, 0.0000, 0.0000). This means that the x-axis of ModCylinder is aligned with the x-axis of the world. The next line rotates ModCylinder 90° around its y-axis. This rotates the axes of ModCylinder as well. The last two lines show that the x-axis of ModCylinder is now the vector (0.0000, 0.0000, -1.0000). This means that the x-axis of ModCylinder now is aligned with the negative z-axis of the world.

member("Engine").model("ModCylinder").transform.identity()
pull member("Engine").model("ModCylinder").transform.xAxis
-- vector( 1.0000, 0.0000, 0.0000 )
member("Engine").model("ModCylinder").rotate(0, 90, 0)
pull member("Engine").model("ModCylinder").transform.xAxis
-- vector( 0.0000, 0.0000, -1.0000 )

**xtra**

**Usage**

-- Lingo syntax
_player.xtra[xtraNameOrNum]

// JavaScript syntax
_player.xtra[xtraNameOrNum];

**Description**

Player property; provides indexed or named access to the Xtra extensions available to the Director player. Read-only.

The xtraNameOrNum argument is either a string that specifies the name of the Xtra extension to access or an integer that specifies the index position of the Xtra extension to access.

The functionality of this property is identical to the top level xtra() method.

**Example**

This statement sets the variable myXtra to the Speech Xtra extension:

-- Lingo syntax
myXtra = _player.xtra["SpeechXtra"]

// JavaScript syntax
var myXtra = _player.xtra["SpeechXtra"];
xtraList (Movie)

Usage

-- Lingo syntax
_movie.xtraList

// JavaScript syntax
_movie.xtraList;

Description

Movie property; displays a linear property list of all Xtra extensions in the Movies/Xtras dialog box that have been added to the movie. Read-only.

Two possible properties can appear in xtraList:

- #filename—Specifies the filename of the Xtra extension on the current platform. It is possible to have a list without a #filename entry, such as when the Xtra extension exists only on one platform.
- #packageurl—Specifies the location, as a URL, of the download package specified by #packagefiles.
- #packagefiles—Set only when the Xtra extension is marked for downloading. The value of this property is another list containing a property list for each file in the download package for the current platform. The properties in this subproperty list are #name and #version, which contain the same information as found in xtraList (Player).

Example

This statement displays the xtraList in the Message window:

-- Lingo syntax
put(_movie.xtraList)

// JavaScript syntax
put(_movie.xtraList);

See also

Movie, xtraList (Player)

xtraList (Player)

Usage

-- Lingo syntax
_player.xtraList

// JavaScript syntax
_player.xtraList;

Description

Player property; displays a linear property list of all available Xtra extensions and their file versions. Read-only.

This property is useful when the functionality of a movie depends on a certain version of an Xtra extension.
There are two possible properties that can appear in `xtraList`:

- `#filename`—Specifies the filename of the Xtra extension on the current platform. It is possible to have a list without a `#filename` entry, such as when the Xtra extension exists only on one platform.
- `#version`—Specifies the same version number that appears in the Properties dialog box (Windows) or Info window (Macintosh) when the file is selected on the desktop. An Xtra extension may not necessarily have a version number.

**Example**

This statement displays in the Message window all Xtra extensions that are available to the Director Player.

```
-- Lingo syntax
trace(_player.xtraList)

// JavaScript syntax
trace(_player.xtraList);
```

### y (vector)

**Usage**

```
member(whichCastmember).vector.y
member(whichCastmember).vector[2]
```

**Description**

3D property; allows you to get or set the `y` component of a vector.

**Example**

This statement shows the `y` component of a vector:

```
vec = vector(20, 30, 40)
put vec.y
-- 30.0000
```

### yAxis

**Usage**

```
member(whichCastmember).transform.yAxis
```

**Description**

3D transform property; allows you to get but not set the vector representing the transform’s canonical `y`-axis in transform space.
Example

The first line of this example sets the transform of the model ModCylinder to the identity transform. The next two lines show that the Y axis of ModCylinder is the vector (0.0000, 1.0000, 0.0000). This means that the y-axis of ModCylinder is aligned with the y-axis of the world. The next line rotates ModCylinder 90° around its x-axis. This rotates the axes of ModCylinder as well. The last two lines show that the y-axis of ModCylinder is now the vector (0.0000, 0.0000, 1.0000). This means that the y-axis of ModCylinder now is aligned with the positive z-axis of the world.

```lisp
member("Engine").model("ModCylinder").transform.identity()
put member("Engine").model("ModCylinder").transform.yAxis
-- vector( 0.0000, 1.0000, 0.0000 )
member("Engine").model("ModCylinder").rotate(90, 0, 0)
put member("Engine").model("ModCylinder").transform.yAxis
-- vector( 0.0000, 0.0000, 1.0000 )
```

yon

Usage

```lisp
member(whichCastmember).camera(whichCamera).yon
```

Description

3D property; allows you to get or set the distance from the camera defining where along the camera's Z axis the view frustum is clipped. Objects at a distance greater than yon are not drawn.

The default value for this property is 3.40282346638529e38.

Example

This statement sets the yon property of camera 1 to 50000:

```lisp
member("3d world").camera[1].yon = 50000
```

See also

hither

z (vector)

Usage

```lisp
member(whichCastmember).vector.z
member(whichCastmember).vector[3]
```

Description

3D property; allows you to get or set the z component of a vector.

Example

This statement shows the z component of a vector:

```lisp
vec = vector(20, 30, 40)
put vec.z
-- 40.0000
```
**zAxis**

**Usage**

```
member(whichCastmember).transform.zAxis
```

**Description**

3D transform property; allows you to get but not set the vector representing the transform's canonical z-axis in transform space.

**Example**

The first line of this example sets the transform of the model ModCylinder to the identity transform. The next two lines show that the z-axis of ModCylinder is the vector (0.0000, 0.0000, 1.0000). This means that the z-axis of ModCylinder is aligned with the z-axis of the world. The next line rotates ModCylinder 90° around its y-axis. This rotates the axes of ModCylinder as well. The last two lines show that the z-axis of ModCylinder is now the vector (1.0000, 0.0000, 0.0000). This means that the z-axis of ModCylinder now is aligned with the x-axis of the world.

```
member("Engine").model("ModCylinder").transform.identity()
put member("Engine").model("ModCylinder").transform.zAxis
-- vector( 1.0000, 0.0000, 0.0000 )
member("Engine").model("ModCylinder").rotate(0, 90, 0)
put member("Engine").model("ModCylinder").transform.zAxis
-- vector( 0.0000, 0.0000, -1.0000 )
```
